This Patent is brought to you for free and open access by the Technology Transfer at STARS. It has been accepted for inclusion in UCF Patents by an authorized administrator of STARS. For more information, please contact lee.dotson@ucf.edu.
Abstract

Methods, systems and compositions are disclosed wherein normal, non-transformed, healthy biological cells are protected from oxidative stress, radiation therapy and chemotherapy while diseased, transformed cells, such as cancer cells, are provided no protection by the biocompatible, polymer coated nanoceria composition of the present invention. The polymer-coated nanoceria preparation herein exhibits no toxicity to normal cells and exhibits pH-dependent antioxidant properties at neutral or physiological pH values, between approximately 6.5 to approximately 11.0 and is inactive as an antioxidant at acidic pH values between approximately 2.0 to approximately 6.4. Improved therapeutic agents and cytoprotecting devices are based on the newly discovered, pH-dependent properties of polymer-coated nanoceria that provide selective cytoprotection.

POLYMER COATED CERIA NANOPARTICLES FOR SELECTIVE CYTOPROTECTION

RELATED APPLICATIONS

The present application claims the benefit of priority from U.S. Provisional Patent Application Ser. No. 60/1049,953 filed on Jul. 26, 2007 and is a continuation-in-part of U.S. patent application Ser. No. 11/965,343 filed on Dec. 27, 2007, both applications are incorporated herein by reference. This invention was made with Government support under Agency contract number K01 CA101781 awarded by the National Institutes of Health. The government has certain rights in this invention.

FIELD OF THE INVENTION

This invention relates to biological uses of nanoceria particles, and in particular to methods, systems and compositions useful in the synthesis of polymer coated ceria oxide nanoparticles for biomedical applications.

BACKGROUND AND PRIOR ART

Cerium is a silvery metallic element, belonging to the lanthanide group. Cerium oxide (CeO₂/Ce₂O₃) is used in precision polishing and lapping applications. Ultra fine nanosize cerium oxide, less than 10 nanometers, is more efficient for coating purposes. Recently, it was reported by B. Rzigalinski et al. that nanoparticles prolong the life of cortical neurons in culture 4 fold over the cells without treatment, decrease the intracellular Ca²⁺ concentration and prevent UV damage of cortical neurons. See B. Rzigalinski et al., "Cerium Oxide Nanoparticles Extend Cell Longevity and Act as Free Radical Scavengers" at website http://www.med.miami.edu/nmbws/Rzigalinski112.html. Based on its chemical characteristics, this effect is partially due to a decrease of reactive oxygen species (ROS).

Various investigators have shown that nanoceria particles possess antioxidant properties and have demonstrated the survival of neuron cells in cultures against oxidative stress and radiation.

However, the synthetic procedures for nanoceria reported so far are not likely to be approved by the U.S. Food and Drug Administration (FDA) because the synthesis procedures involve the use of surfactants and other toxic materials.

In addition, the published synthetic methods result in uncoated nanoparticles that are not stable and tend agglomerate in aqueous solutions.

Further developments in biomedical research reveal the efficacy of coated magnetic nanoscale particle compositions for therapeutic uses. In Patent Publication WO/2003/005029 to Zhenghe Xu et al. iron and iron oxide particles are coated with dextran for biological cell separation using magnetic carrier technology. The dextran coating is used to prevent mechanical instability of the particle in suspension.

U.S. Patent Publication 2003/0124,194 to Graw et al. discloses amine functionalized superparamagnetic nanoparticles using a process that consists of coating the magnetic nanoparticles with a carboxylated polymer then subsequently reacting the carboxylated functionalized magnetic nanoparticles with carbodiimide and a large excess of diamine, after which the amine-terminated nanoparticles are reacted with bifunctional crosslinking agents and various biomolecules.

U.S. Patent Publication 2005/0130167 to Gang Boa, et al. provides multifunctional magnetic nanoparticle probe compositions for molecular imaging and monitoring wherein the magnetic nanoparticle has a biocompatible coating, such as, dextran, thereof.

U.S. Patent Publication 2006/0014938 to Groman et al. describes stable aqueous colloidal lanthanide oxides, including cerium oxide, some of which are associated with a polymer including dextran. The colloidal compositions are useful as imaging agents in technology requiring injectable chemicals for contrast agents. There is no mention of cerium oxide coated with polymers having autocatalytic and antioxidant properties.

U.S. Patent Publication 2006/0142749 to Robert Ivkov discloses thermotherapeutic compositions for treating disease. The thermotherapeutic compositions include magnetic nanoparticles that may be coated to enhance the heating properties of a bioprobe, particularly if the coating is a polymeric material that can include dextran.

Thus, polymeric coatings including dextran have been reported for use on magnetic nanoparticles and the results seem promising in molecular imaging, monitoring and therapeutic treatment of disease.

In addition, prior to the present invention, most synthetic procedures for nanoceria resulted in nanoparticles with poor water solubility and provided ceria particles that precipitate from aqueous solutions. Also, prior art synthetic procedures involve the use of toxic solvents, therefore hindering their potential clinical use.

It is desirable to find reliable solutions to use of nanoceria particles with antioxidant properties in the treatment of many human diseases that are due to the death of cells in specific tissues or organs. The majority of those diseases are due to accumulation of metabolic insults from reactive oxygen species originating within or outside of the cells. These diseases include all forms of blindness whether hereditary, light-induced, or physical damage such as occurs in retinal detachment. In addition, damage due to ageing, stroke, cardiac infarction, burns, etc which proceed through reactive oxygen species, can be addressed with the nanoceria particles synthesized according the present invention.

The ability of nanoceria particles to reversibly switch from Ce³⁺ to Ce⁴⁺ is a key factor in their use in catalytic and biological applications as antioxidants. In co-pending U.S. application Ser. No. 11/965,343 filed on Dec. 27, 2007, it was reported that the polymeric coating does not affect the autocatalytic properties of nanoceria, as hydrogen peroxide and peroxyl radicals can diffuse through the hydrophilic polymer coating and oxidize Ce³⁺ to Ce⁴⁺. Thus, polymer-coated nanoceria nanoparticles are used as antioxidants in biomedical applications, such as, protection against radiation damage, oxidative stress and inflammation.

The present application shows that polymer-coated nanoceria particles with enhanced biocompatibility and stability in aqueous solution exhibit a pH-dependent antioxidant activity and provide a means for tailoring reversible and non-reversible antioxidant properties of polymer-coated nanoceria particles.

SUMMARY OF THE INVENTION

The objectives of U.S. application Ser. No. 11/965,343 filed on Dec. 27, 2007, are also objectives of the present invention and are listed below.

A primary objective of the present invention is to provide a facile, synthetic method for the formation of cerium oxide (ceria) nanoparticles coated with a biodegradable polymer.

A secondary objective of the present invention is to provide a synthetic method for the formation of cerium oxide (ceria)
A third objective of the present invention is to provide cerium oxide (ceria) nanoparticles coated with a biodegradable polymer that has physical properties that are substantially identical to the properties of uncoated nanoceria particles for therapeutic applications.

A fourth objective of the present invention is to provide cerium oxide (ceria) nanoparticles coated with a biodegradable polymer with good solubility and stability in water and phosphate buffered saline, with no precipitation for approximately 12 months.

A fifth objective of the present invention is to provide a facile, synthetic method for the formation of cerium oxide (ceria) nanoparticles coated with dextran that is further crosslinked with epichlorohydrin and treated with ammonia, resulting in an amminated dextran coated ceria nanoparticles to create a targetable ceria nanoparticle.

A sixth objective of the present invention is to provide a water stable, biodegradable polymer coated nanoceria preparation that is biologically active for administration to human and other mammals.

A seventh objective of the present invention is to provide a water stable, biodegradable polymer coated nanoceria preparation that has a long circulation time, such as, a plasma half-life longer than one minute.

An eighth objective of the present invention is to provide a facile, synthetic method for the formation of cerium oxide (ceria) nanoparticles coated with polyacrylic acid polymer that will result in a carboxyl group functionalized nanoparticle. The ceria nanoparticles coated with functionalized carboxyl groups are reacted with a diamine, such as ethylenediamine, to create an amine functionalized cerium oxide nanoparticle without the need for polymeric crosslinking.

Additional objectives of the continuation-in-part application are as follows:

A ninth objective of the present invention is to provide polymer coated ceria nanoparticles formed in situ for use in improved therapeutic agents and cytoprotecting devices.

A tenth objective of the present invention is to provide a biocompatible nanoceria preparation that protects normal cells against oxidative stress, while providing no cytoprotection to cancer or malignant cells.

An eleventh objective of the present invention is to provide a pH-dependent therapeutic agents and devices using polymer coated ceria nanoparticles that selectively protect healthy tissue and cells from free radicals, but do not protect transformed cell lines due to the acidic microenvironment of the transformed cells.

A twelfth objective of the present invention is to provide polymer coated ceria nanoparticles that exhibit reversible and non-reversible antioxidant behavior.

A preferred in situ method for the synthesis of a plurality of cerium oxide nanoparticles coated with a biodegradable polymer for antioxidant, free-radical scavenging and autacatalytic biomedical applications, includes preparing an aqueous cerium nitrate solution, mixing the aqueous cerium nitrate solution with a biodegradable polymer to form a first mixture, adding the first mixture dropwise to an ammonium hydroxide solution while continuously stirring to form a second mixture, centrifuging the second mixture containing ammonium hydroxide to settle any debris or large particles, purifying the centrifuged mixture by ultrafiltration, and recovering a plurality of non-agglomerated cerium oxide nanoparticles coated with the biodegradable polymer wherein the antioxidant, free-radical scavenging and autacatalytic properties of the cerium oxide nanoparticles are unchanged from uncoated cerium oxide nanoparticles.

The preferred in situ synthesis method has a biodegradable polymer that is at least one of a carbohydrate polymer, a synthetic polyol, a carboxylated polymer, and derivatives thereof, more preferably, the carboxylated polymer is polyacrylic acid.

It is also preferred that the carboxylated polymer is reacted with a diamine selected from at least one of ethylene diamine, propylene diamine and hexane diamine, to provide an amminated cerium oxide nanoparticle in a reaction that eliminates the need for polymer crosslinking.

The preferred carbohydrate polymer for the in situ synthesis method of the present invention is a polysaccharide, such as dextran, arabinogalactan, chitosan and the like; most preferably the polysaccharide is dextran.

In the preferred in situ synthesis method the cerium nitrate solution contains approximately 2.0 to approximately 3.0 grams of cerium nitrate to approximately 5 ml of water and the plurality of dextran-coated cerium oxide nanoparticles has a UV profile exhibiting strong absorption below approximately 400 nm with peak absorption at approximately 300 nm.

A preferred composition that is useful as a potent antioxidant in biomedical applications includes a plurality of nanoceria particles coated with a biodegradable polymer selected from at least one of a carbohydrate polymer, a synthetic polyol, a carboxylated polymer, and derivatives thereof. The preferred carboxylated polymer is polyacrylic acid.

A preferred composition of matter that is useful as an antioxidant, free-radical scavenger and autacatalyst in biomedical applications includes a plurality of nanoceria particles coated with a crosslinked-carboxylated biodegradable polymer selected from at least one of a carbohydrate polymer, a synthetic polyol, a carboxylated polymer, and derivatives thereof.

The preferred composition has a plurality of dextran coated cerium oxide nanoparticles that form a colloidal suspension that is stable in water and form a colloidal suspension that is stable in a phosphate buffer saline solution.

A more preferred composition of matter that is useful as an antioxidant, free-radical scavenger and autacatalyst in biomedical applications includes a plurality of nanoceria particles coated with a crosslinked-carboxylated biodegradable polymer selected from at least one of a carbohydrate polymer, a synthetic polyol, a carboxylated polymer, and derivatives thereof. The preferred carbohydrate polymer is a polysaccharide such as, dextran, arabinogalactan and chitosan; most preferably, the polysaccharide is dextran.

In the preferred composition, the plurality of dextran coated cerium oxide nanoparticles has a UV profile exhibiting strong absorption below approximately 300 nm and the physical properties of the dextran coated cerium nanoparticles replicate the physical properties of the uncoated nanoceria particles for therapeutic applications as antioxidants, free-radical scavengers and autacatalytic agents.

In the preferred composition, the plurality of dextran coated cerium oxide nanoparticles form a colloidal suspension that is stable in water and form a colloidal suspension that is stable in a phosphate buffer saline solution.

A more preferred composition of matter that is useful as an antioxidant, free-radical scavenger and autacatalyst in biomedical applications includes a plurality of nanoceria particles coated with a crosslinked-carboxylated biodegradable polymer selected from at least one of a carbohydrate polymer, a synthetic polyol, a carboxylated polymer, and derivatives thereof. The preferred carbohydrate polymer is a polysaccharide such as, dextran, arabinogalactan and chitosan; the most preferred polysaccharide is dextran.

The preferred composition has a plurality of dextran coated cerium oxide nanoparticles with a UV profile exhibiting strong absorption below approximately 400 nm with peak absorption at approximately 300 nm.
Further objects and advantages of the present invention will be apparent from the following detailed description of a presently preferred embodiment which is illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 shows the UV-visible absorption spectrum of the dextran coated nanoceria prepared in the present invention.

FIG. 2 is the fluorescence spectra of dextran coated cerium oxide nanoparticles ($\lambda_{ex}=283$ nm) showing a characteristic fluorescence peak at approximately 410 nanometer (nm) wavelength.

FIG. 3 shows the measurement of zeta-potential in the analysis of the stability of nanoparticle preparation against agglomeration within biological systems.

FIG. 4 shows the X-ray diffraction pattern of nanocrystalline cerium oxide coated with dextran in the present invention.

FIG. 5 shows the X-ray photon spectroscopy spectrum of the synthesized cerium oxide nanoparticles coated with dextran showing the presence of a mixed valence (Ce$^{3+}$ and Ce$^{4+}$) state.

FIG. 6A is a photographic image of a first solution of dextran coated nanoceria after ultrafiltration with an Amicon 30K filter.

FIG. 6B is a photographic image of a second solution of dextran coated nanoceria after the solution is concentrated using a 30K Centricon concentrator.

FIG. 7A is a transmission electron microscopy (TEM) image of the dextran coated ceria nanoparticles showing the size and dispersity of the ceria crystals.

FIG. 7B is a high resolution transmission electron microscopy (HRTEM) image of the dextran coated ceria nanoparticles showing that the coating does not affect the crystallinity.

FIG. 7C is a selected area electron diffraction (SAED) image of a single ceria crystal showing that the dextran coated ceria crystal is a face-centered cubic (FCC) phase crystal.

FIG. 8 is a graph showing the increase in particle size with time upon concanavalin addition.

FIG. 9 is a graph showing reversible and successive shift in transmittance of dextran coated nanoceria particles after adding hydrogen peroxide (Days 1-10).

FIG. 10A is a real-time image of dextran nanoceria solutions without hydrogen peroxide on the left and with hydrogen peroxide on the right at day one.

FIG. 10B is a real-time image of dextran nanoceria solutions without hydrogen peroxide on the left and with hydrogen peroxide on the right at day three.

FIG. 10C is a real-time image of dextran nanoceria solutions without hydrogen peroxide on the left and with hydrogen peroxide on the right at day seven.

FIG. 10D is a real-time image of dextran nanoceria solutions without hydrogen peroxide on the left and with hydrogen peroxide on the right at day ten.

FIG. 10E is a real-time image of dextran nanoceria solutions without hydrogen peroxide on the left and with hydrogen peroxide on the right at day ten after adding fresh hydrogen peroxide.

FIG. 10F is a real-time image of dextran nanoceria solutions without hydrogen peroxide on the left and with hydrogen peroxide on the right at day twenty.

FIG. 11A is a graph showing the percent viability of normal cardiomyocyte cell cultures untreated and treated with dextran coated nanoparticles, hydrogen peroxide and a combination of dextran coated nanoparticles and hydrogen peroxide.

FIG. 11B is a graph showing the percent viability of normal dermal fibroblasts cell cultures untreated and treated with dextran coated nanoparticles, hydrogen peroxide and a combination of dextran coated nanoparticles and hydrogen peroxide.

FIG. 12 is an X-ray photon spectroscopy (XPS) spectra of the aminated nanoceria showing the presence of a mixed valence, Ce$^{3+}$ and Ce$^{4+}$ similar to the spectrum of dextran coated nanoceria that is not aminated.

FIG. 13 is an X-ray photon spectroscopy (XPS) spectrum of the polyaacrylic acid coated nanoceria (PAA-nanoceria) showing the presence of a mixed valence, Ce$^{3+}$ and Ce$^{4+}$ similar to the spectrum of dextran coated nanoceria and aminated dextran coated nanoceria shown in FIG. 12.

FIG. 14 is a diagram depicting the in-situ formation of stable cerium oxide nanoparticles coated with dextran polymer as stabilizer.

FIG. 15 is a Fourier Transform Infrared (FT-IR) spectra of pure dextran and dextran-coated cerium oxide nanoparticles.

FIG. 16 is an FT-IR spectra of a representative dextran coated nanoceria preparation compared to that of pure dextran, indicating the presence of characteristic dextran IR bands in dextran coated nanoceria.

FIG. 17A shows reversible color changes in a solution of dextran-coated nanoceria at pH 7.4, on addition of hydrogen peroxide.

FIG. 17B shows irreversible color changes in a solution of dextran-coated nanoceria at pH 4.0, on addition of hydrogen peroxide.

FIG. 18 is a graph of the transmittance spectra showing reversible autocatalytic behavior for dextran coated nanoceria when incubated with hydrogen peroxide at pH 7.4.

FIG. 19 is a graph of the transmittance spectra showing irreversible autocatalytic behavior for dextran coated nanoceria when incubated with hydrogen peroxide at pH 4.0.

FIG. 20 shows the effect of dextran-coated nanoceria on lung carcinoma.

FIG. 21 shows the effect of dextran-coated nanoceria on breast carcinoma cells.

FIG. 22 is a graph showing the percent viability of normal cardiomyocyte cell cultures protected from nitroxyl radical induced toxicity when treated with dextran coated nanoparticles versus no treatment with dextran coated nanoceria.

FIG. 23 is a graph showing the percent viability of normal cardiomyocyte cell cultures protected from nitroxyl radical induced toxicity when treated with aminated dextran coated nanoparticles versus no treatment with aminated dextran coated nanoceria.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Before explaining the disclosed embodiments of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangements shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

The term “nanoceria” is used interchangeably with “cerium oxide nanoparticles” and is used to refer to the cerium oxide particles of multiple valences.

The term “biodegradable polymer” is used herein to describe a class of polymers that are non-toxic to mammals and the environment and more specifically, include dextran, derivatives of dextran such as reduced dextran, carboxyl methyl reduced dextran, a polyol polymer or carbohydrate polymer, synthetic polyols, carboxylated polymers, such as
polyacrylic acid, and other polysaccharides, such as, but not limited to, arabino-galactan, and chitosan as disclosed in Gro- 
man et al. U.S. Patent Publication 2006/0014938 and Gav et 

In the present invention, the cerium oxide nanoparticles or 
nanoceria are polymer associated, or, in other words, coated 
with a biodegradable polymer. The polymer confers stability 
in water and can be functionalized with carboxylic or amino 
groups for conjugation with proteins, peptides, oligonucleo-
tides, small molecules, and the like.

Further, as will be explained in detail, the antioxidant activ-
ity of the polymer coated nanoceria particles is significantly 
reduced in a acidic pH, from approximately 2 to approxi-
mately 6; however, in the pH range from approximately 7 to 
approximately 11, the polymer-coated nanoceria particles are 
very active antioxidants, thus permitting the design of 
therapeutic devices, such as, in the radio-protection of 
healthy tissue during radiation therapy of acidic tumors.

In general, the polymer coated nanoceria particles of the 
present invention each have a size between approximately 1 
nanometer (nm) to approximately 500 nm in diameter, pref-
erably between approximately 1 nm and approximately 10 
nm. For example, the nanoceria particles used herein are 
composed of a cerium oxide core that is approximately 4 
nanometers (nm) in diameter surrounded by a dextran coating 
for a total nanoparticle size of approximately 10 nm in diam-
eter, as illustrated in FIG. 10.

Briefly, an aqueous solution of cerium nitrate and dextran is 
added to an ammonia solution under continuous stirring. 
Upon formation of the cerium oxide nanocrystals, molecules 
of dextran coat the nanoparticle surface, preventing further 
growth and resulting in dextran coated nanoceria. FIG. 8 
shows time dependent size increase that is observed on con-
canavalin A induced clustering of dextran nanoceria in phos-
phate buffered saline (PBS).

Further stabilization and functionalization of the nanopar-
ticle is achieved by crosslinking the dextran coating with epichlorohydrin, followed by treatment with ammonia to yield 
amminated dextran-coated nanoceria (ANC) as illustrated in 
FIG. 15.

Methods of preparing the biodegradable polymer coated 
cerium oxide compositions for use as an antioxidant and 
protection from damaging ultra violet (UV) radiation are 
provided in detail below.

The first embodiment of the present invention provides an 
in situ method and procedure for synthesizing a biodegrad-
able polymer coated ceria nanoparticle for antioxidant and 
autocatalytic biomedical applications.

The second embodiment of the present invention provides a 
method and procedure for synthesizing aminated cross-
linked dextran coated ceria nanoparticles for antioxidant and 
autocatalytic biomedical applications.

The third embodiment of the present invention provides a 
method and procedure for synthesizing aminated cross-
linked dextran coated ceria nanoparticles for antioxidant and 
autocatalytic biomedical applications.

The examples below provide further detail on the synthesis 
and physical characterization of the biodegradable polymer 
coated ceria nanoparticles of the present invention. Dextran is 
used as an exemplary polymeric coating, not a limitation of 
the present invention; other biodegradable polymers may be 
judicially selected by a person of skill in the art.

Example 1

Synthesis of Dextran Coated Ceria Nanoparticles

Under ambient conditions, a 1 M cerium nitrate solution 
(2.17 g in 5 ml of water) was mixed with a 1M Dextran T-10 
(5 g in 10 ml of water) to form mixture (I). Under continuous 
stirring, the mixture (I) is then added dropwise to 30 ml of 
29% ammonium hydroxide solution (Fischer, USA) forming 
mixture (II). Mixture (II) is then stirred continuously for 24 
hours. After 24 hours of stirring, the solution turns from a 
light yellow to a deep brown color. The preparation is centri-
guged at a rate of 4000 rpm for two 30-minute cycles to settle 
down any debris and large particles. The preparation is then 
purified from free dextran by ultrafiltration using a 30 K 
Amicon filter.

Example 2

Crosslinking and Amination of Dextran Coated Ceria 
with Epichlorohydrin

Dextran coated ceria nanoparticles are crosslinked with 
epichlorohydrin using the following procedure under ambient 
conditions:

To 3 ml (3 volume) of dextran coated cermia particle 
preparation in Example 1, 5.5 ml (5 volumes) of 5M NaOH are 
added while stirring. Then, 2 ml (2 volumes) of epichloro-
hydrin are added to the stirring solution. The ceria nanopar-
ticle suspension is stirred vigorously for 8 hours at room 
temperature. Then, 8.5 ml (8.5 volumes) of 30% ammonia is 
added and stirred overnight at room temperature. The next 
day, the excess epichlorohydrin and ammonia are removed by 
ultrafiltration and the nanoparticle buffer is exchanged to 
0.025 M Na-Citrate buffer pH 8. At this point, the aminated 
dextran nanoceria preparation can be concentrated without 
precipitation of the nanoparticles.

Epichlorohydrin is used as the crosslinking agent in 
Example 2, however, it is understood by those skilled in the 
art that other crosslinking agents may be used, such as glut-
araldehyde, bromide derivatives of cyanogens and the like.

The dextran-coated nanoceria (DNC) and aminated dext-
ran-coated nanoceria (ANC) preparations are both stable in 
water and phosphate buffered saline (PBS) at concentrations 
of 40 mM or higher with no precipitation for months. DNC 
and ANC demonstrate good water stability even after several 
heating cycles (70 to 80° C.) and no sedimentation of nano-
particles in PBS or citrate buffer is observed upon centrifuga-
tion at 8,000 rpm for 30 minutes. These characteristics 
make the water-based in situ method advantageous over 
organic solvent based preparations, which are prone to aggre-
gation when suspended in aqueous media. The ANC prepara-
tion has, on average, 3.4 mM of amine per gram of cerium 
that could be used to conjugate targeting ligand and dyes to 
allow optical tracking of the nanoparticles.

It is a primary concern that the physical properties of the 
biodegradable polymer coated ceria nanoparticles remain 
unaffected by the coating which improves handling and appli-
cation for biomedical purposes.

In FIG. 1, the UV profile for the dextran coated nanoceria 
is shown. Dextran coated ceria particles show strong absorp-
tion below 400 nm with peak absorption maximum at 300 nm. 
The UV profile of the dextran coated nanoceria prepared in 
the present invention is similar to that obtained in previous 
work showing that naked or uncoated ceria nanoparticles 
have well defined peak absorption around 305 nm. Thus, the 
UV profile of the coated and uncoated nanoceria is substan-
tially the same.

In FIG. 2 the fluorescence spectra of dextran coated nano-
ceria particles of the present invention has a characteristic 
fluorescence peak around 410 nm and is similar to the fluo-
rescence spectra of the uncoated nanoceria particles reported
The zeta potential of the present invention has a value of -5.7 mV. If the solution is shifted toward more positive and less negative values, the zeta potential would be shifted toward more positive and less negative values. The dextran-coated cerium nanoparticles of the present invention have a zeta potential of -5.7 mV.

Due to the presence of dextran polymer on the surface of the nanoparticle, its charge distribution would be affected and the zeta potential would be shifted toward more positive and less negative values. The dextran-coated cerium nanoparticles of the present invention have a zeta potential of -5.7 mV as shown in FIG. 3.

The X-ray diffraction (XRD) pattern for the dextran-coated cerium nanoparticles is shown in FIG. 4. The XRD pattern indicates that the nanoparticles are amorphous and in good agreement with those found in bulk cerium oxide. The XRD pattern also shows a broad peak at 2θ = 28°, which is in good agreement with the (220) plane of cerium oxide.

The high crystallinity of the nanoceria particles of the present invention is shown in FIG. 6B. The selected area electron diffraction (SAED) pattern of the nanoceria is shown in FIG. 7C. The SAED pattern shows a single diffraction ring, indicating the high crystallinity of the nanoceria.

Further characterization of the dextran-coated cerium nanoparticles was performed using high angle annular dark field transmission electron microscopy (HAADF-STEM). The STEM image shows that the nanoparticles are highly crystalline and have a uniform size distribution.

Concanavalin A is a protein with four binding sites, known to bind carbohydrates. This protein has been used to induce the clustering of dextran-coated gold nanoparticles and most recently it was used in the clustering of iron oxide nanoparticles. It is used to study how the clustering phenomenon changes the optical (gold nanoparticles) or magnetic (iron oxide) properties of the nanoparticles. It is used to verify whether the dextran is associated to (coating) the nanoparticle. In these studies, dextran-coated cerium nanoparticles incubated with concanavalin A and a time-dependent increase in the particle size is observed as measured by dynamic light scattering (DLS). This increase in “size” by light scattering is not due to an increase in the size of the nanoparticles, but rather is due to the clustering of the nanoparticles in solution. FIG. 8 shows that after 90 minutes incubation with concanavalin A, nanoparticle clusters of 650 nm in size are observed, showing the increase in particle size with time upon concanavalin addition.

The addition of glucose to the nanoceria preparation before concanavalin incubation abrogated the assembly of the nanoparticles, suggesting that the observed changes in particle size distribution were due to the concanavalin-dextran interaction on the nanoparticle surface.

Autocatalytic behavior of dextran-coated nanoceria was studied with addition of hydrogen peroxide. One of the most interesting properties of nanoceria is its autocatalytic behavior. The ability of these nanoparticles to reversibly switch from Ce³⁺ to Ce⁴⁺ is a key factor for their biological applications as an antioxidant, among others. Therefore, it is determined whether the dextran coating on the nanoceria preparation compromises its autocatalytic behavior. In these experiments, the nanoparticles are oxidized using hydrogen peroxide. It is observed that after adding hydrogen peroxide, as an oxidizer, to the nanoceria there is a red shift and also color changes to dark orange/brown (Ce⁴⁺). As the hydrogen peroxide decomposes from the nanoparticle suspension, the observed brown color starts to disappear and the solution color returns to yellow (Ce³⁺) within ten days as shown in FIG. 9. In FIG. 9, the reversible and successive shift in transmittance of dextran-coated nanoceria particles after adding hydrogen peroxide on day one, % transmittance plotted against the wavelength, is between approximately 475 nm to approximately 700 nm, at day 2, % transmittance is between approximately 410 nm to approximately 600 nm, day 3, % transmittance is between 400 nm and approximately 550 nm; 5 days 4-10 d, after the addition of hydrogen peroxide and the decomposition of hydrogen peroxide nears completion, the plot of % transmittance against wavelength is within a narrower range between approximately 400 nm and approximately 450 nm wavelength, confirming the disappearance of the brown color.

Autocatalytic activity is represented in Equation (1) below:

\[
2\text{Ce}^{3+}(\text{aq}) + \text{H}_2\text{O}_2(\text{aq}) + 2\text{H}^+(\text{aq}) \rightarrow 2\text{Ce}^{4+}(\text{aq}) + 2\text{H}_2\text{O}
\]
ments, normal human cell cultures are exposed to hydrogen peroxide. This treatment causes a high level of cellular stress, most of them survive this harsh treatment when in the presence of buffers, such as

FIGS. 9, 10A to 10F demonstrate the reversibility of the antioxidant activity of polymer-coated nanoceria solutions at normal physiological conditions. Subsequent addition of hydrogen peroxide in FIG. 10E, after 10 days, brought the color of the solution back to orange/brown which again started to disappear within the next 10 days (FIG. 10F). This reversible and cyclical autocatalytic behavior at physiological conditions is essential for free radical scavenging and antioxidant properties of nanoceria and its potential medical applications.

With regard to biological activity, preliminary biological data shows that, as expected, the dextran-coated nanoceria preparation act as potent antioxidant agents. In these experiments, normal human cell cultures are exposed to hydrogen peroxide. This treatment causes a high level of cellular stress, similar to that experienced by cells under oxidative damage. The data show that in the absence of dextran nanoceria (DNC), from approximately 50% to approximately 95% of the cells died upon addition of hydrogen peroxide, whereas most of them survive this harsh treatment when in the presence of dextran coated nanoceria (DNC).

FIGS. 11A and 11B are graphs of percent viability of normal cell cultures, cardiomyocytes and dermal fibroblast, respectively. In FIGS. 11A and 11B, the control is untreated and thus 100% viable; the cells treated with dextran coated nanoceria (DNC) are 100% viable and the cells treated with a combination of dextran coated nanoparticles (DNC) and hydrogen peroxide are 100% viable. However, FIG. 11A shows that normal cell cultures of cardiomyocytes are approximately 5% viable when treated with or exposed to only hydrogen peroxide and FIG. 11B shows that normal cell cultures of dermal fibroblasts are approximately 50% viable when treated with hydrogen peroxide without dextran coated ceria nanoparticles (DNC). Thus, FIGS. 11A and 11B are graphical illustrations of the effectiveness of dextran coated ceria nanoparticles as potent antioxidant agents that promote 100% cell viability in the presence of deadly oxidizing agents.

The crosslinking and amination of dextran coated ceria with epichlorohydrin as discussed in Example 2 above, was studied to determine whether the anti-oxidant properties of the nanoceria particles could be extended to injectable or implantable biomedical applications.

The dextran coated nanoceria prepared according to Example 1 shows great stability in water and various aqueous buffers, such as 0.1 M phosphate buffer, pH 7.4, without compromising its autocatalytic and antioxidant properties. However, the surface of this nanoparticle cannot be easily modified with targeting ligands such as peptides, oligonucleotides and proteins. To advance these studies, the polymeric dextran coating has been crosslinked on the surface of the ceria particle using epichlorohydrin and further derivatized its surface with ammonia to yield an aminated dextran coated nanoceria. As discussed earlier, it is known in the art to use other crosslinking agents and the present invention incorporates by reference, other known crosslinking agents, such as, but not limited to, glutaraldehyde, bromide derivatives of cyanogens, and the like.

Preliminary characterization of this preparation shows that indeed the dextran surface contains reactive amino groups that can be used to conjugate targeting ligands and various dyes, including near infrared dyes that would allow in vivo optical tracking of the nanoparticle. Furthermore, this amine group, which has a positive charge at physiological pH, can be reacted with a succinic anhydride, resulting in a carboxylated or negatively charged nanoceria preparation, greatly expanding the conjugation capabilities of the aminated preparation.

FIG. 12 is an X-ray photon spectroscopy (XPS) spectrum of the aminated crosslinked nanoceria showing the presence of a mixed valence, Ce⁴⁺ and Ce³⁺ similar to the spectrum of dextran coated nanoceria that is not aminated.

Physical properties of the aminated dextran coated nanoceria were analyzed by X-ray photon spectroscopy to determine whether the crosslinking procedure would affect the presence of both Ce³⁺ and Ce⁴⁺ and therefore the biological and autocatalytic activity. As shown in FIG. 12, the presence of both Ce³⁺ and Ce⁴⁺ species in the aminated dextran coated nanoceria are similar to those obtained with non-crosslinked nanoceria. This indicates that crosslinking of the dextran does not affect the dual valency (Ce³⁺/Ce⁴⁺) in the nanoceria preparation of the present invention and most likely will not affect its autocatalytic/antioxidant properties. Biological uses of the crosslinked, biodegradable polymer-coated nanoceria include administration to human and other mammals needing antioxidant treatments to prolong cell life.

Example 3

Carboxylated Polymer Coating of Nanoceria Particles

In another embodiment, following the procedure outlined in Example 1, wherein under ambient conditions, a 1 molar solution of a polyacrylic acid is used in place of the 1 molar solution of dextran, nanoceria particles are coated with a biodegradable polymer containing a plurality of carboxylic groups (carboxylated polymer), wherein a portion of the carboxyl groups are associated with the cerium oxide surface and a portion of carboxyl groups are exposed on the nanoparticle surface and available for conjugation. The carboxylated nanoceria can be reacted with a diamine, such as ethylene diamine, and correspondingly converted to an amine functionalized nanoparticle.

Synthesis Method.

The preparation of polyacrylic acid coated nanoceria (PAA-nanoceria) involves the use of cerium (III) nitrate and polyacrylic acid (PAA). 1 M cerium (III) nitrate (Aldrich, 99%) solution (2.17 grams in 5.0 milliliters (ml) of water) was mixed with 0.5 mM solution of PAA (Sigma) to form mixture (I). With continuous stirring, the cerium nitrate and PAA mixture (I), is added drop wise to 30.0 ml of 29% ammonium hydroxide (Sigma Aldrich, 30%) solution to form mixture II. Subsequently, mixture (II) is stirred continuously for 24 hours; at this point, the solution has changed from a light yellow to a deep brown color. Next, the stirred mixture (II) is centrifuged at 4000 rpm for two 30 minute cycles to settle down any debris and large particles. The centrifuged solution is then purified from free PAA by ultrafiltration using 30K molecular weight cut-off Amicon filter (Millipore, Inc.) The resulting negative charge on the PAA-nanoceria is assessed by zeta potential analysis.

Below is a schematic diagram (2) of the synthesis of polyacrylic acid coated nanoceria (PAA-nanoceria).
Note that the nanoparticles are functionalized with carboxylic groups on the surface, which allows conjugation of peptides, DNA oligonucleotides, proteins and small molecules for targeting applications, without the need for crosslinking the polymer.

Furthermore, the carboxylic groups on the polyacrylic acid nanoceria can be converted to reactive amine groups by the reaction with a water soluble diamine, such as ethylene diamine, in the presence of a water soluble carbodiimide as disclosed in Gaw et al., U.S. Patent Publication 2002/0124194 for coating of iron oxide nanoparticles as MRI contrast agents.

PAA-nanoceria possesses similar autocatalytic activity as regular, non-coated nanoceria, dextran coated nanoceria, and aminated dextran coated nanoceria. In addition, PAA-nanoceria contains both Ce⁴⁺ and Ce³⁺ (mixed valance) on the nanoparticle which is important for its autocatalytic and antioxidant activity as shown in FIG. 13. The X-ray particle spectroscopy (XPS) image of polyacrylic acid coated nanoceria (PAA-nanoceria) in FIG. 13 is substantially similar to the X-ray photon spectroscopy (XPS) image of dextran coated nanoceria and aminated dextran coated nanoceria shown in FIG. 12. This indicates that the PAA-nanoceria will behave like the other polymer coated nanoceria preparations disclosed herein.

Prior to the present invention, a facile, cost effective, nontoxic synthesis of biodegradable polymer coated nanoceria particles was not available. The synthesis does not require surfactants or vigorous experimental conditions and the end-product is suitable for unlimited biomedical applications.

Prior to the present invention, it was not known that a biodegradable polymeric coating of ceria nanoparticles would not affect the autocatalytic and antioxidant properties of the ceria nanoparticles.

A biodegradable polymer coated nanoceria exhibits good solubility and stability in water and phosphate buffer saline. The preparation has good stability over many days in the buffer solution which is advantageous over the preparations which aggregate when redispersed in aqueous media. This characteristic makes them suitable for biomedical applications and clinical use. Further, there is no problem with agglomeration in aqueous solution over a long period of time, as with preparations using a sol-gel technique as reported by H. S. Potdar et al. in Materials Chemistry and Physics, 2002, 74, 306.

Further advantages of the biodegradable polymer coated cerium oxide nanoparticle include a suspension that can be concentrated using ultrafiltration devices without agglomeration of the nanoparticles.

With regard to the second embodiment, the dextran coating on the nanoparticle can be crosslinked with epichlorohydin and ammonia, resulting in an aminated dextran coated ceria nanoparticles. The major benefit of the crosslinked dextran coating is the ability to form conjugates with various ligands, such as peptides, antibodies, DNA-oligonucleotides, proteins and small molecules, to create a targetable ceria nanoparticle. This would allow targeting or "homing" of the nanoparticle to the corresponding site of inflammation or disease.

All embodiments of the present invention are useful in forming colloidal compositions which include nanoparticle suspensions of cerium oxide coated with a biodegradable polymer. The resulting colloidal composition is highly stable in water and water-based buffers, such as phosphate saline buffer and the like. The colloidal compositions are also suitable for concentration and sterilization by filtration.

Similar procedures have been used in the preparation of carboxylated coated iron oxide nanoparticles, allowing for the creation of targeted molecular imaging agent for MRI as reported in Gaw et al. U.S. Patent Publication 2003/0124194; the teaching with regard to use of carboxylated polymers is incorporated herein by reference.

Some dextran coated iron oxide nanoparticles have been approved by the FDA for various applications including MRI imaging of lymph nodes as reported by M. G. Harisinghani, et al. in New England it of Medicine 2003, 348, 2491.

The newly developed synthesis of biodegradable polymer coated ceria nanoparticles presented herein would be ideal for clinical applications and a candidate for FDA approval. It was an unexpected finding that the physical properties of the biodegradable polymer coated ceria nanoparticles remain unaffected by the polymeric coating which substantially improves handling and application for antioxidant and autocatalytic biomedical applications.

Thus, polymer-coated and functionalized nanoceria particles show great stability with no precipitation for more than six months stored at room temperature. FT-IR spectra shown in FIG. 16 confirms the presence of dextran coating on the coated ceria nanoparticles confirming that dextran is a vital part of the nanoparticles, since characteristic IR peaks of dextran are also present in the dextran-coated nanoceria (DNC) spectrum. The FT-IR analysis reveals the presence of dextran in the synthesized nanoceria and substantiates the complete surface passivation of the ceria nanocrystal by dextran.

The great stability with no precipitation and the presence of dextran as an integral part of the ceria nanoparticles supports a finding of high stability of the DNC under physiological conditions and testing of dextran-coated nanoceria solution in phosphate-buffered saline (PBS) in a pH range of approximately 7.4 to approximately 11.0 where reversible antioxidant behavior is observed.

New Properties of Polymer-Coated Cerium Oxide Nanoparticles.

Under acidic pH conditions, polymer-coated cerium oxide nanoparticles do not exhibit reversible antioxidant behavior. Figs. 17B and 19 show that at pH 4.0, the oxidation capability of dextran-coated nanoceria (DNC) is not reversible, in contrast to Figs. 17A and 18 where the tests were conducted at neutral pH or alkaline conditions which are comparable to physiological conditions.

In FIG. 17A, the addition of hydrogen peroxide at ten-day intervals caused the slightly yellow solution to turn to an orange/brown color, gradually returning to the slightly yellow color in a reversible cycle. FIG. 18 is the XPS spectra showing changes in % transmittance (a-e) based on the changes in the amount of Ce³⁺ and Ce⁴⁺ at pH 7.4. The control shows transmittance before the addition of hydrogen peroxide; b shows transmittance immediately after addition of hydrogen peroxide; c is transmittance after 24 hours; d is transmittance after 3 days and e is transmittance after seven days.

\[
\text{Ce(NO}_3\text{)}_3 + 2\text{NH}_2\text{OH} \rightarrow \text{Ce(OH)}_3 + 3\text{HNO}_3 + 2\text{H}_2\text{O} \quad (2)
\]
FIG. 17B shows that at pH 4.0 (acidic conditions), DMC does not exhibit a significant red shift upon addition of hydrogen peroxide, even though the color of the solution has turned slightly orange. Surprisingly, after 24 hours, the solution turned completely clear and a significantly large blue shift was observed. In FIG. 19, the control represents transmittance before the addition of hydrogen peroxide, g is transmittance immediately after addition of hydrogen peroxide and h is the transmittance curve after 24 hours and after 3 days.

After ten days, the solution remained clear and the addition of more hydrogen peroxide did not bring either the color of the solution back to orange or have any effect on the transmittance curve. Furthermore, once the pH of dextran nanoceria preparation was lowered to 4.0, the autocatalytic activity could not be reversed, even on raising the pH to 7.4, showing irreversibility at acidic pH values, such as 4.0.

Further evidence of the nonreversibility at acidic pH is shown in Table 1 below.

### Table 1

In Table 1 above, XPS studies of DMC at pH 7.4 and pH 4.0 revealed similar amounts of Ce³⁺ and Ce⁴⁺ at both pH values in the initial samples. Upon addition of hydrogen peroxide, a similar increase in the amount of Ce⁴⁺ was observed at both pH values. However, note that ten days after addition of hydrogen peroxide, DMC at pH 7.4 is able to regenerate returning to values for Ce³⁺ and Ce⁴⁺ similar to those in the initial sample, confirming the reversibility of the system at pH 7.4. In contrast, DMC is unable to regenerate at pH 4.0, keeping a relatively high amount of Ce⁴⁺ after 10 days, confirming the nonreversibility of Ce³⁺ and Ce⁴⁺ values at an acidic pH.

It has been proposed that the antioxidant properties of nanoceria are due to the presence of mixed valence states (Ce³⁺/Ce⁴⁺) on the nanoparticle surface that allow for the scavenging of free radicals. During the scavenging process, Ce³⁺ ions are converted to Ce⁴⁺, as shown in schematic diagram (3) below.

\[
\text{CeO}_2 + 2[\text{OH}^-] \rightarrow 2\text{CeO}_2 + \text{H}_2\text{O} \\
\text{Ce}^{2+} + \text{H}_2\text{O} \rightarrow \text{Ce}^{3+} + \text{H}^+ + \epsilon \\
\text{Ce}_3\text{O}_4 + \text{O}_2 + 2\text{H}^+ \rightarrow 2\text{Ce}_2\text{O}_3 + \text{H}_2\text{O}
\]

The system is regenerated via a series of surface chemical reactions between ions in solution (such as H⁺) and the Ce⁴⁺ ions on the nanoparticle surface, where they are converted back to Ce²⁺, and therefore allows for the scavenging of more free radicals. Theoretically, the low-pH environment inter-
that selectively protect healthy tissue from free radicals, which might be elevated during chronic inflammation or during radiation therapy and chemotherapy while permitting transformed or diseased cells in an acidic microenvironment to be eradicated. The selective protection of nontransformed, healthy cells surrounding a diseased site minimizes adverse side effects of aggressive therapeutic treatments, such as radiation therapy and chemotherapy.

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it has presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

We claim:

1. A process for protecting normal, non-transformed biological cells using a pH-dependent therapeutic agent, comprising:

- providing a plurality of biocompatible, polymer-coated cerium oxide nanoparticles having a pH-dependent antioxidant property, said polymer-coated cerium oxide nanoparticles being an active antioxidant in pH range from 7 to approximately 11 while having a substantially reduced antioxidant activity at an acidic pH from approximately 2 to 6, said polymer-coated cerium oxide nanoparticles not able to reversibly switch from Ce³⁺ to Ce⁴⁺ at said acidic pH; and
- adding an effective amount of said polymer-coated cerium oxide nanoparticles to a cell environment containing normal biological cells and diseased biological cells so as to contact said normal biological cells and diseased biological cells, thereby selectively protecting said normal, non-transformed cells from hydroxyl-radical induced oxidative, nitroxyl-radical induced oxidative stress, radiation therapy, inflammation or chemotherapy, while providing no cytoprotection to said diseased cells.

2. The process of claim 1, wherein the normal biological cells have a pH value between approximately 6.5 to approximately 11.0 and the diseased biological cells have a pH value between approximately 2.0 and approximately 6.4.

3. The process of claim 1, wherein the plurality of biocompatible, polymer-coated cerium oxide nanoparticles are coated with a biodegradable polymer selected from at least one of a carbohydrate polymer, a synthetic polyo, a carboxylated polymer, and derivatives thereof.

4. The process of claim 1, wherein the polymer-coated cerium oxide nanoparticles are coated with a crosslinked-amminated biodegradable polymer selected from at least one of a carbohydrate polymer, a synthetic polyo, a carboxylated polymer and derivatives thereof.

5. The process of claim 1 wherein the normal biological cells include cardiomyocytes, dermal fibroblasts, lung tissue cells or breast tissue cells.

6. The process of claim 1, wherein the diseased biological cells include lung cancer cells, breast cancer cells, or dermal cancer cells.

7. The process of claim 3, wherein the biodegradable polymer is polyacrylic acid or polysaccharide.

8. The process of claim 7, wherein the polysaccharide is dextran.

9. The process of claim 3, wherein a colloidal suspension formed by the polymer-coated cerium oxide nanoparticles is stable in water or phosphate buffer solution.

10. The process of claim 4, wherein the biodegradable polymer is polyacrylic acid or polysaccharide.

11. The process of claim 10, wherein the polysaccharide is dextran.

12. The process of claim 4, wherein a colloidal suspension formed by the polymer-coated cerium oxide nanoparticles is stable in water or phosphate buffer solution.
