ABSTRACT

Laser pumping and flashlamp pumping of apatite crystals such as trivalent neodymium-doped strontium fluorapatite (Sr₅(PO₄)₃F) emits efficient lasing at both 1.059 and 1.328 μm. The pump sources for the SFAP material doped with Nd³⁺ includes pulsed Cr:LiSrAlF₆ tuned to approximately 805.4 nm. Alternatively, similar results occurred using a continuous wave laser source of Ti:sapphire tuned to approximately 805.4 nm. A preferred embodiment includes a resonant cavity with a high reflectivity mirror having a reflectivity of 100% and an output coupler mirror with a reflectivity of less than 100%. An optional tuning component such as a Pockels Cell-Polarizer combination can also be included. The SFAP material doped with Nd³⁺ exhibits a large absorption cross section, high emission cross section, and long radiative lifetime.

1 1.3 µM LASERS USING Nd³⁺ DOPED APATITE CRYSTALS

This application is a continuation of application Ser. No. 08/383,954, filed Feb. 6, 1995. now abandoned.

This invention relates to apatite crystalline laser materials, and in particular to trivalent neodymium-doped strontium fluorapatite (SFAP) with high efficiency lasing at 1.059 and 1.328 µm.

BACKGROUND AND PRIOR ART

Solid-state lasers based on rare-earth doped crystal have been becoming substantially more significant. These types of systems are increasingly becoming more common in industrial, medical, scientific and military applications. The diverse nature of applications requires the availability of wide ranges of varieties of laser materials that can operate over wide wavelengths. However, most crystal materials are limited to operation over narrow ranges of wavelengths. For example, Nd-doped Y₃Al₅O₁₂ (Nd:YAG) is the most common type of laser material, owing to its high emission cross section, relatively long energy storage time, and robust thermomechanical properties. The usual output wavelength for Nd:YAG is approximately 1.064 µm. Other crystal materials have also been doped with Nd and are limited in wavelength operation.

SFAP crystals doped with neodymium. Nd, also referred to as Sr₅(PO₄)₃F and neodymium-doped strontium fluorapatite were successfully grown more than twenty years ago. See U.S. Pat. Nos. 3,504,300; 3,505,239; and 3,617,937 each to Mazelsky et al., which are each incorporated by reference. These references described that SFAP and other apatite crystals such as Calcium Fluorapatite(CAP), Ca₅(PO₄)₃F grown at that time some twenty years ago were limited in lasing at approximately 1.059 µm. U.S. Pat. No. 5,341,389 to Payne et al. issued in August of 1994, which is also incorporated by reference. Further described another apatite crystal Sr₅(VPO₄)₃F (SVAP) that exhibits lasing at approximately 1.059 µm.

SUMMARY OF THE INVENTION

The first objective of the present invention is to provide SFAP crystal doped with trivalent neodymium, Nd³⁺ that exhibits efficient lasing at approximately 1.3 µm.

The second objective of this invention is to provide an SFAP crystal material doped with trivalent neodymium, Nd³⁺ that exhibits efficient lasing approximately at both 1.059 and 1.3 µm.

The invention includes laser and flashlamp for pumping apatite crystals such as trivalent neodymium-doped strontium fluorapatite (Sr₅(PO₄)₃F) that lases approximately at both 1059 and 1.3 µm. The laser sources include pulsed Cr:LiSrAlF₆ tuned to approximately 805.4 nm. Alternatively, similar results occurred using a continuous wave laser source of Ti:sapphire tuned to approximately 805.4 nm. Alternatively, lasing occurred using a flashlamp pump source. A preferred embodiment includes a resonant cavity with a high reflectivity mirror having a reflectivity of 100% and an output coupler mirror with a reflectivity of less than 100%. An optional timing component such as a Pockels Cell-Polarizer can also be included.

Further objects and advantages of this invention will be apparent from the following detailed description of a presently preferred embodiment which is illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 shows the π and σ room temperature polarized emission spectra of Nd³⁺:SFAP in the 800 nm region.

FIG. 2 shows the π and σ room temperature polarized emission spectra of Nd³⁺:SFAP in the 1.06 and 1.3 µm region obtained by continuous wave excitation at 805.4 nm.

FIG. 3A shows the plot of the laser output energy of Nd³⁺:SFAP and Nd³⁺:YVO₄ for the pulsed operation.

FIG. 3B shows the plot of the laser output power of Nd³⁺:SFAP and Nd³⁺:YVO₄ for continuous wave operation.

FIG. 4A shows the plot of the laser output energy as a function of the flashlamp energy of Nd³⁺:SFAP at 1059 nm.

FIG. 4B shows the plot of the laser output energy as a function of the flashlamp energy of Nd³⁺:SFAP at 1328 nm.

FIG. 5A shows the plot of laser output energy of Nd³⁺:SFAP in Q-switched operation at 1059 nm.

FIG. 5B shows the plot of laser output energy of Nd³⁺:SFAP in Q-switched operation at 1328 nm.

FIG. 6 is a schematic diagram of a Nd³⁺:SFAP laser in Q-switched operation.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Before explaining the disclosed embodiment of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangement shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

The trivalent neodymium-doped strontium fluorapatite crystal (Nd³⁺ doped SFAP) or Nd³⁺:Sr₅(PO₄)₃F can be synthetically grown utilizing known techniques such as the Czochralski method similar to the one disclosed in U.S. Pat. Nos. 3,504,300; 3,505,239; and 3,617,937 each to Mazelsky et al., which are each incorporated by reference. Here an SFAP sample containing 0.68 at. % Nd³⁺ ((1.4x10¹⁰ Nd³⁺ ions/cm³) ) was used for laser-pumped laser testing with a peak absorption coefficient of 25.7 cm⁻¹.

Room temperature polarized absorption spectra of Nd³⁺:SFAP in the 800 nm region are given in FIG. 1. The peak absorption coefficient is 2.74 cm⁻¹ for a sample containing 0.2 mole % Nd³⁺ in the melt. Since the distribution coefficient of Nd³⁺ ions in SFAP is 0.36, the actual Nd³⁺ concentration in this crystal is approximately 0.072 at. %. As a result, Nd³⁺:SFAP has an absorption cross section of 2.26x10⁻¹⁹ cm².

Room temperature polarized emission spectra of Nd³⁺:SFAP are shown in FIG. 2. In FIG. 2, the emission is partially polarized with the π polarization stronger than the σ polarization with Room temperature emission decay of 0.072 at. % Nd³⁺:SFAP is exponential with a decay time of 298 µs.

Here an SFAP sample containing 0.68 at. % Nd³⁺ ((1.4x10¹⁰ Nd³⁺ ions/cm³) ) was used for laser-pumped laser testing with a peak absorption coefficient of 25.7 cm⁻¹. The room temperature emission decay from the 4F₅/₂ manifold is non-exponential in this sample, and, by normalizing the fluorescence intensity at t=0 to one and then integrating the entire decay curve over time, the decay time was found to be only 190 µs. This indicates the existence of concentration quenching in this SFAP crystal. The decay time measurements were done with fine-ground powders of SFAP crystals to avoid the decay time lengthening effect of self-absorption.

For laser experiments, a 1.9 mm-long sample of the 0.68 at. % Nd³⁺:SFAP crystal was cut with flat and parallel faces containing the c-axis. Both pulsed and continuous wave (cw) laser-pumped laser experiments were performed which simulated diode laser pumping. Pulsed laser action was
excited with a long pulse Cr:LiSrAlF₆ (Cr:LiSAF) laser. The Cr:LiSrAlF₆ laser was tuned to the Nd:SFAP absorption peak at 805.4 nm with a spectral bandwidth of approximately 1 nm. Continuous wave (cw) excitation was achieved with a CW Ti:Sapphire (containing wave titanium sapphire) laser tuned to 805.4 nm with a spectral bandwidth of approximately 0.1 nm. More than 95% of the pump power was absorbed in both pump schemes. The laser resonator was composed of a 5 cm radius of curvature high reflectance (HR) mirror coated for the wavelength of interest and a flat output coupler (OC) with a transmission up to 5%. The pump light was focussed with a 10 cm focal length lens through the HR mirror to a point near the side of the laser crystal facing the output coupler (OC).

Nd³⁺:SFAP produced lasing that is linearly polarized along the c axis and occurs at 1.059 µm for the 4F₃/2 to 4I₁/₂ transition. Table I lists the thresholds and slope efficiencies for both the pulsed and continuous wave operations comparing Nd:SFAP at 1.059 µm and Nd:YVO₄ at 1.0646 µm. Table I compares these different crystals for output coupler (OC) transmissions of 1.2, 3, and 5%.

The stimulated emission cross section of Nd³⁺:SFAP has been measured to be 5.4x10⁻¹⁹ cm² at 1.059 µm. As a result, the product of the stimulated emission cross section and the radiative decay time for Nd:SFAP is about 1.5 times that of Nd:YVO₄. Concentration branching exists in the SFAP crystal used in the lasing experiment but was negligible in the tested Nd:YVO₄ sample. However, both crystals performed almost identically at 1.06 µm lasers in our experiments. Thus, it is more than probable that SFAP will outperform YVO₄ for comparable Nd³⁺ concentrations.

FIG. 3A shows the plot of the output energy of Nd³⁺:SFAP for the pulsed operation. In FIG. 3A, the laser output energy is plotted as a function of absorbed energy for a 5% Output Coupler (OC). FIG. 3B shows the plot of the output power of Nd³⁺:SFAP and Nd³⁺:YVO₄ for continuous wave operation. In FIG. 3B, the laser output power is plotted as a function of absorbed power for a 5% Output Coupler (OC). The measured slope efficiency can be expressed as a function of the transmission of the OC. In equation (1) as follows:

\[ \eta_s = \eta_r/T + L, \]

where \( \eta_r \) is the intrinsic slope efficiency, and \( L \) is the double-pass passive loss. In Table 1, the parameters \( \eta_r=71% \) and \( L=0.93% \) can be used for pulsed operation, and \( \eta_r=64% \) and \( L=0.62% \) can be used for continuous wave (cw) operation for Nd:SFAP.

The performance of the Nd:SFAP was assessed by comparing Nd:SFAP with a 2.7 mm-long Nd:YVO₄ crystal purchased from ITT Electro-Optics Corp. The emission decay time of Nd³⁺ ions in the Nd:YVO₄ crystal was measured to be 98 µs, which is about the same as its radiative lifetime indicating negligible concentration quenching. The Nd:YVO₄ crystal has a peak absorption coefficient of 17.4 cm⁻¹ at 808.7 nm. The Nd³⁺ number density was estimated to be 7x10¹⁹ ions/cm³ according to the absorption data. The laser output was \( \pi \)-polarized and occurred at 1.0646 µm. However, the laser output power varied from region to region in the crystal indicating inhomogeneities. The results obtained from the best performing region are summarized in Table I for comparison.

The Nd:YVO₄ laser input/output characteristics are also given in FIG. 3A and FIG. 3B for a 5% OC. While the Continuous Wave (cw) performances for both crystals are almost identical, the pulsed slope efficiencies for YVO₄ are slightly lower than those for SFAP. Analysis of the slope efficiency as a function of the OC transmission for Nd:YVO₄ yields \( \eta_s=68% \) and \( L=1.18% \) for pulsed operation, and \( \eta_s=64% \) and \( L=0.67% \) for cw operation. The stimulated emission cross section of Nd:SFAP has been estimated by the inventors hereof to be 5.4x10⁻¹⁹ cm² at 1.059 µm. As a result, the product of the stimulated emission cross section and the radiative decay time for Nd:SFAP is about 1.5 times that of Nd:YVO₄. Concentration branching exists in the SFAP crystal used in the lasing experiment but was negligible in the tested Nd:YVO₄ sample. However, both crystals performed almost identically at 1.06 µm lasers in our experiments. Thus, it is more than probable that SFAP will outperform YVO₄ for comparable Nd³⁺ concentrations.

FIG. 4A shows the plot of the output energy of Nd³⁺:SFAP at 1059 nm in flashlamp pumped laser operation. FIG. 4B shows the plot of the laser output energy of Nd³⁺:SFAP at 1328 nm in flashlamp pumped laser operation. Referring to FIGS. 4A and 4B, it is apparent that 2.7 J for 1.059 µm and 1.8 J for 1.328 µm have been obtained.

FIG. 5A shows the plot of laser output energy of Nd³⁺:SFAP in Q-switched operation for 1059 nm. FIG. 5B shows the plot of laser output energy of Nd³⁺:SFAP in Q-switched operation for 1328 nm. From FIGS. 5A and 5B, it is apparent that 150 mJ for 1.059 µm and 100 mJ for 1.328 µm have been obtained.

FIG. 6 is a schematic diagram of a Nd³⁺:SFAP pump in Q-switched operation. Laser source or flashlamp 100 can be a pulsed or continuous laser pump or flashlamp as described above, for pumping laser medium, 200.SFAP which is positioned within a cavity formed from mirrors 300 and 600. The Q-switch device such as a Pockels Cell-Polarizer 400, 500.
combination, mode-locker, etalon, and other known types of shutters. 600 refers to Output Coupler (OC) mirror having a reflectivity of less than 100%. Although, pump source 100 is shown as transverse mounted, source 100 could pump longitudinally through high reflection mirror 300.

Although the preferred embodiments described above refer to specific types of pulsed and continuous wave laser sources, and a flashlamp, other laser sources such as but not limited to diode laser source can be used.

Applications using 1.3 micrometer lasers based on the invention include but are not limited to fiber optic communications and cable television using the fundamental frequency, high power frequency doubled lasers for photodynamic therapy, frequency conversion based on 1.3 µm and dual wavelength lasers.

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it has presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

We claim:
1. A method of simultaneously lasing an apatite crystal at 1.06 and 1.3 µm, comprising the steps of:
(a) emitting optical radiation from a pump source the pump source being tuned to approximately 805.4 nm chosen from one of a pulsed Cr:LiSrAlF₆ laser and a continuous wave Ti:Sapphire laser; and
(b) pumping a gain medium in a resonator cavity with the optical radiation, the gain medium composed of trivalent neodymium-doped strontium fluorapatite crystal (SFAP doped with Nd³⁺), the crystal being antireflection coated at both 1.06 and 1.3 µm; and
(c) extracting simultaneous peak emissions having wavelengths of approximately 1.06 and approximately 1.3 µm from the resonator cavity.

2. The method of simultaneously lasing an apatite crystal of claim 1, wherein the resonator cavity includes:
(a) a first reflectivity mirror having a reflectivity of approximately 100%;
(a) a Q-switch chosen from at least one of: a pockels cell-polarizer, mode locker, and an etalon, the Q-switch positioned between the first reflectivity mirror and the gain medium; and
(b) an output coupler mirror having a reflectivity of less than approximately 100% connected to the gain medium.

3. A laser system for simultaneously outputting peak wavelength emissions of 1.06 and 1.3 µm comprising:
an excitation laser source for generating optical radiation, the laser source being tuned to approximately 805.4 nm chosen from one of a pulsed Cr:LiSrAlF₆ laser and a continuous wave Ti:Sapphire laser;
a gain medium in a resonator cavity, the gain medium composed of an apatite crystal chosen from one of: Nd³⁺:Sr₅(PO₄)₃F, Nd³⁺:Ca₅(PO₄)₃F and Nd³⁺:Sr₅(VO₄)₃F, the crystal being antireflection coated at both 1.06 and 1.3 µm, the gain medium being pumped by the generated optical radiation; and
means for outputting peak wavelength emissions of approximately 1.06 and 1.3 µm from the resonator cavity.

4. The laser of claim 3, wherein the resonator cavity includes:
a first reflectivity mirror having a reflectivity of approximately 100%;
a Q-switch chosen from at least one of: a pockels cell-polarizer, mode locker, and an etalon, the Q-switch positioned between the first reflectivity mirror and the gain medium; and
an output coupler mirror having a reflectivity of less than approximately 100% connected to the gain medium.

5. A laser system for simultaneously outputting peak wavelength emissions of 1.06 and 1.3 µm comprising:
an excitation laser source for generating optical radiation, the laser source being tuned to approximately 805.4 nm chosen from one of a pulsed Cr:LiSrAlF₆ laser and a continuous wave Ti:Sapphire laser;
a gain medium in a resonator cavity, the gain medium composed of trivalent neodymium-doped strontium fluorapatite crystal (SFAP doped with Nd³⁺), the crystal being antireflection coated at both 1.06 and 1.3 µm, the gain medium being pumped by the generated optical radiation; and
means for outputting peak wavelength emissions of approximately 1.06 and 1.3 µm from the resonator cavity.
