Abstract

Methods of destroying toxic volatile air-borne toxins are disclosed. In a preferred embodiment, a piece of formaldehyde laden substrate (wood) such as paneling and furniture is treated with TiO₂ solution to form a thin and translucent veneer on the surface. This layer acts like a membrane preventing outward transport of formaldehyde and other harmful compounds produced by weatherization and natural degradation of the substrate. In a preferred embodiment the photocatalytic destruction of formaldehyde is achieved. Other toxins destroyed include terpenes and other types of toxic volatile organic compounds (VOCs). While the preferred embodiment is applied to wood based supports such as paneling and furniture, the invention has applicability for other surfaces such as caskets and roof shingles. For example, the TiO₂ coating can be used on flexible paper type face masks in order to destroy air-borne toxic compounds such as formaldehyde and the like that are used in medical environments where embalming procedures using toxins such as formaldehyde are used.

PHOTOCATALYTIC FACE MASK

This is a Divisional of application Ser. No. 08/403,305 filed Mar. 14, 1995, now U.S. Pat. No. 5,604,339.

This invention relates to photocatalysts, and in particular to titanium dioxide \( \text{TiO}_2 \) and in situ applications that are applied to the surface of wooden and polymer based materials as a photocatalyst for inhibiting the emission of harmful toxic volatile organic compounds (VOCs) such as formaldehyde and wood borne VOCs such as (\( \alpha \)-pinene, \( \beta \)-pinene and limonene).

BACKGROUND AND PRIOR ART

Toxic volatile organic compounds (VOCs) such as formaldehyde are increasingly prevalent in indoor air in both residential and industrial settings. Formaldehyde is used in manufacturing of resins, plastics, rubber, textile finishes and especially wood based products. Urea formaldehyde and melamine-formaldehyde resins are known for the release of formaldehyde. In particular, formaldehyde is released by the offgassing from urea-formaldehyde foam that is used as insulation for homes and businesses as well as carpet padding. Formaldehyde is also released by the offgassing from urea-formaldehyde bonded chipboard that is used in furniture manufacturing and for building materials. Other undesirable toxins emitted from wood are monoterpenes which are a natural byproduct of wood devolatilization.

Major terpenic VOCs which are the natural toxic byproducts of wood devolatilization when wood is exposed or degraded include \( \alpha \)-pinene, \( \beta \)-pinene, limonene, camphene, and fenchone.

The Clean Air Act of 1990 requires minimization of discharges to the environment and limiting VOC emissions. The detoxification of hazardous compounds generated within a given medium will require an oxidative process to "turn off" the pollutant species.

A substance that can mediate oxidation of the environmental pollutants to deep oxidation by-products such as \( \text{CO}_2 \) and \( \text{H}_2\text{O} \) would be desirable. In general, this implies the use of oxidizing agents such as ozone and hydrogen peroxide. However, these two oxidizing agents alone are not capable of total destruction of the contaminants.

Currently, the most advanced technology for the reduction of VOCs is regenerative catalytic oxidation (RCO).

Coupling light with an oxidant such as ozone \( \text{O}_3 \), hydrogen peroxide \( \text{H}_2\text{O}_2 \), titania \( \text{TiO}_2 \), and others referred to as advanced oxidation processes (AOPs) has been shown to accomplish deep oxidation of all carbonaceous species to \( \text{CO}_2 \). In heterogeneous photocatalysis, the oxidation process is aided by using photocatalysts such as \( \text{TiO}_2 \), zinc oxide (ZnO) and the like. For example, \( \text{TiO}_2 \) particles are readily activated upon exposure to near UV radiation (wavelengths below \( 365 \text{ nm} \)) producing electron/hole \((e^-/h^+)\) pairs on the semiconductor surface. The electrons and holes act as strong reducing and oxidizing agents that facilitate mineralization of the target organics via formation of active species such as superoxide ion radical \((\text{O}_2^-)\), hydroxyl radical \((\text{OH})\), and peroxyl radical \((\text{HO}_2)\) on the semiconductor surface. For example, conduction band electrons \((e^-_{cb})\) can reduce molecular oxygen to reactive radicals as follows:

\[
e^-_{cb} + \text{O}_2 \rightarrow \text{O}_2^- \\
\text{O}_2^- + \text{H}^+ \rightarrow \text{HO}_2^- \\
2\text{HO}_2^- \rightarrow \text{O}_2 + \text{H}_2\text{O}_2 \\
\text{H}_2\text{O}_2 \rightarrow 2\text{OH}^-
\]

Table 1 depicts the relative oxidizing power of surface borne radicals compared with other commonly used oxidants. See Harris, J. C., Ozonation, In Unit Operations for Treatment of Hazardous Industrial Wastes, Noyes Data Corporation, Park Ridge, N.J., 1978. It can be seen that the oxidizing power of hydroxyl radicals is highest among all transhalogen oxidants and surpassed only by fluorsine. The valence band holes \((h^+)\) can also oxidize water to produce hydroxyl radicals, where the net effect can be complete oxidation or full mineralization of target organics.

\[
h^+ + \text{H}_2\text{O} \rightarrow \text{H}^+ + \text{OH}^-
\]

The net effect is generally complete oxidation and full mineralization of target organics. Titania-catalyzed photo-oxidation processes combine light-assisted interactions of both homogeneous and heterogeneous nature. In addition, the combination of photons and the semiconductor photocatalyst results in new reaction pathways (i.e., photoreduction of oxygen by conduction band electrons and photooxidation by valence band holes) unavailable in non-catalytic photolysis. Reactive species (e.g. superoxide anion and hydroxyl radicals, etc.) are produced photolytically on the surface of the catalyst in the presence of water vapor and/or oxygen molecules eliminating the need for addition of active oxidants such as ozone and hydrogen peroxide. Also, the catalytically active surfaces that exist on titania influence the photodegradation kinetics and the extent of conversion of the target organic molecules. These factors combine to produce many opportunities and process flexibility to affect conversion efficiencies as well as the selectivities of the photocatalytic process. Unlike thermocatalytic processes, the photocatalytic process actually benefits from high moisture content of the media within which toxins reside as the hole oxidation of water generates highly reactive \( \text{OH}^- \) species that attack target organics.

Thus, the need exists to develop a more effective process for the detoxification of manufactured and wood borne toxic emissions such as formaldehyde and terpenes.

SUMMARY OF THE INVENTION

The first objective of the present invention is to provide a photocatalyst material to act as a chemical membrane that mineralizes and neutralizes organic toxins released from the product material.

The second object of this invention is to provide a chemical membrane application for wood support materials that will neutralize the emission of formaldehyde and terpenic emissions from the wood based materials.

The third object of this invention is to provide a \( \text{TiO}_2 \) (titania) based surface treatment, that acts as a photocatalyst for inhibiting the emission of harmful volatile organic compounds (VOCs) from a support material.

The fourth object of this invention is to provide a \( \text{TiO}_2 \) treatment that acts as a photocatalyst for inhibiting the...
emission of formaldehyde and terpenic emissions from the wood support materials.

The fifth object of this invention is to provide a chemical membrane application for wood support materials that will neutralize the emission of formaldehyde and terpenic emissions from the wood support materials.

The sixth object of this invention is to provide a titania treatment for the surface of wood that can both protect the polymeric surface and inhibit the emission of hazardous compounds.

The seventh object of this invention is to provide a titania treatment for wood surfaces that acts as a trap for absorbing toxins in indoor air and neutralizing them.

The eighth object of this invention is to provide a titania treated face mask that acts as a trap for absorbing toxins in indoor air and neutralizing them.

A preferred method includes steps of applying titania to wood, fabric and cellulose fiber surfaces. The first step applies a TiO₂ membrane to the sample to achieve the destruction of toxic VOCs such as but not limited to formaldehyde. Titania such as Degussa P25™, is mixed with water to make a uniform suspension (ratio TiO₂ to water=1:5-10 by weight). The second step is to clean (i.e. degrease) the surface to which catalyst will be applied by using a suitable solvent such as acetone, ethanol and the like. The third step is to dry the surface at room temperature to remove solvents. The fourth step is to uniformly spray the aqueous titania suspension over the woody surface to achieve loading density of approximately 1 to 2 g/m². Alternatively, a thickness of approximately 0.6-1.2 micrometer is used for a dry condition. The fifth step is to dry the surface at approximately room temperature or an ambient temperature of approximately 25° to 30° C. The sixth step is to pass the coated surface along with an acrylic or silicone film through a press roller to finalize fixation of the catalyst to the surface. Alternatively, other membranes that are also UV transparent and permeable, and the like can be used in place of silicone film. The treatment can be applied to commercially produced wood surfaces such as but not limited to panelling, fabric coated furniture and caskets. The treatment can also be applied to face mask to protect wearers from toxic VOCs.

Further objects and advantages of this invention will be apparent from the following detailed description of the presently preferred embodiment which is illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 illustrates formaldehyde destruction utilizing application of the subject invention.

FIG. 3B is the spectral power emitted by the sun that contains radiation that is capable of activating TiO₂ and producing active radicals.

FIG. 4 is an absolute spectral power distribution of a commercial fluorescent lamp capable of activating titania and producing active species such as hydroxyl, peroxyl, and superoxide ion radicals that readily oxidize formaldehyde and other organics.

FIG. 5 depicts the gaseous concentration of formaldehyde in the ambient air emitted form a piece of virgin wood sample exposed to periods of dark and light.

FIG. 6 is a graph of the restfits of the exposure of TiO₂ treated wood sample to periods of dark and light.

FIG. 7A is a graph of typical indoor concentration of H₂O as well as the photocatalytic water vapor generated from titania-coated wood samples during periods of dark and light exposure as shown by water vapor concentration, ppmv verses elapsed time in minutes.

FIG. 7B is a graph of typical indoor concentration of formaldehyde, carbon monoxide and carbon dioxide as shown by gas concentration, ppmv verses elapsed time in minutes.

FIG. 8 shows a preferred flow chart of steps used in applying a TiO₂ membrane to a wood sample to achieve the destruction of formaldehyde and other harmful VOCs.

FIG. 9a shows an embodiment of an application of a TiO₂ membrane to residential wood paneling.

FIG. 9b shows another embodiment of an application of a TiO₂ membrane to a piece of wood furniture.

FIGS. 10A through 10C shows yet a still another embodiment of an application of a TiO₂ membrane to a face mask for keeping out undesirable toxins.

FIG. 11 illustrates a system employed for the photocatalytic oxidation of terpenic VOCs in the presence of oxygen.

FIG. 12 shows a total ion chromatogram of different types of terpenes.

FIG. 13 shows a total ion chromatogram of a dark reactor effluent.

FIG. 14A shows the GC-FID chromatogram of a dark reactor effluent over time.

FIG. 14B shows the GC-FID chromatogram of a light reactor effluent over time.

FIG. 15 shows the Total ion chromatogram of terpenes shown in FIGS. 14A and 14B exposed to VV-excited TiO₂.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Before explaining the disclosed embodiment of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangement shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

The subject invention applies a novel use of the process described in U.S. Pat. No. 5,246,737 by one of the subject inventors thereof, which is incorporated by reference. Patent '737 describes three steps used as a methods of immobilizing semiconductors and noble metals on a wide range of solid surfaces. In step A of the method to immobilize a semiconductor on a support made of polymeric material such as fabric or plexiglass support, a selected polymeric surface of the support is treated with an appropriate solvent.

In step B, a fine (less than approximately one micron particle size) semiconductor powder slurry in the same solvent is then applied to the selected polymeric surface. In step C, the solvent is then removed by drying the polymeric surface with room temperature air. As used herein, treating the support surface means applying a selected solvent which not only cleans but causes the outer layer to swell and be capable of binding fine particles by molecular entanglement, i.e., by wrapping around the fine particles with polymer molecules. Thus, the solvent for the first step is capable of partially or entirely dissolving the support material or other auxiliary material, e.g., silicone polymer, if support is not soluble. When non-soluble natural or synthetic polymers are
employed as the support or other non-soluble materials are used as the support, then the method includes the following step B' which is substituted for step B. In step B', a thin layer of approximately 1 to 100 microns of semiconductor slurry in a solvent containing an appropriate polymer, preferably silicone polymer, is applied to the already treated support surface.

U.S. Pat. No. 5,246,737 further describes that the above method can also be employed to immobilize a semiconductor catalyst such as TiO₂ on a fabric. More specifically, 5 g of silicone, such as silicone rings for example, are exposed to 50 ml of methylene chloride solvent solution in a 200 ml flask for approximately twenty-four hours at room temperature. Solvent containing a relatively small amount of silicone polymer (approximately 0.2 g) is drained out of the flask and is added to 1 g of TiO₂ (Degussa P-25™) to form a slurry. The slurry is applied onto a selected surface of a predetermined component such as but not limited to particle board, a commercial fluorescent lamp capable of activating titania, or other non-soluble materials are the superoxide ion radical generated. Mechanism 3 refers to the hydroxyl radical generated from hydroxyl ion on TiO₂ surface by action of holes. Mechanism 4 refers to the mechanism of hydroxyl radical attack to break formaldehyde absorbed on TiO₂ surface to form formyl radical. Mechanism 5 refers to the formyl radical oxidation by oxidizing species O₂ such as OH-. Intermediate oxidation products, IP, such as formic acid are formed and finally convert to the products of deep oxidation CO₂ and H₂O.

FIG. 2A is a graph of the light intensity measured past titanium coating on the surface of the support in photons per second versus loading density of photocatalyst(TiO₂) in g/cm². FIG. 2A shows that no more than a TiO₂ membrane (veneer) thickness for depositing on the substrate surface of no more than two g of TiO₂ per square meter of substrate is necessary. This corresponds to a film thickness of approximately 1 to 4.5 microns.

FIG. 2B shows the setup used for finding optimum TiO₂ thickness (deposition depth) on the substrate. Photo multiplier 210 is placed beneath quartz plate 220 upon which various TiO₂ loadings (thicknesses) 230 are deposited. UV light 240 is partially absorbed by TiO₂ layer as it passes through to reach photo multiplier 210.

FIG. 3A depicts the absorption spectrum of anatase TiO₂ (the most suitable form of titania for use here). FIG. 3B is a spectrum of energy emitted by the sun and the range of wavelengths in the UV portion of the spectrum that is capable of activating TiO₂ and producing results of toxic VOC destruction. FIG. 3B shows that wavelengths less than approximately 400 nm activate TiO₂. The sun’s spectrum contains enough UV (wavelength in the range of less than 400 nm) to activate titania.

FIG. 4 displays the absolute spectral power distribution of a commercial fluorescent lamp capable of activating titania and producing chemical reactions for the destruction of toxic VOCs. Thus, artificial light is sufficient to activate titania.

FIG. 5 depicts the gaseous concentration of formaldehyde in the ambient air emitted from a piece of a wood sample exposed to periods of dark and light.

FIG. 6 is a graph of the results of the exposure of TiO₂ treated wood sample to periods of dark and light. It is clear that titania coating acts as a membrane capable of breaking down and destroying formaldehyde as it passes through this layer, when illuminated by light. It can be seen that when formaldehyde concentration drops, carbon dioxide concentration increases indicating that CO₂ is formed by action of photocatalytic oxidation of formaldehyde at the wood surface.

FIG. 7 is a graph of the indoor concentration of H₂O as shown by water vapor concentration, ppmv verses elapsed time in minutes. Indoor water vapor concentrations well above 10,000 ppmv are typically present in the air that reach TiO₂ resulting in the formation of active oxidizing species. FIG. 7A also depicts the manner in which water is formed as a by-product of photocatalytic destruction of formaldehyde at the surface of TiO₂ treated wood sample. It can be seen that when TiO₂ treated wood is exposed to the light, H₂O concentrations of the foggis increases. FIG. 7B is a graph of typical indoor concentration of formaldehyde CO and CO₂ as shown by gas concentration, ppmv, verses elapsed time in minutes. FIG. 7B depicts the presence of harmful toxins such as formaldehyde and CO in typical residential room air and also shows the threshold limit value (TLV) for formaldehyde.
mixed with water to make a uniform suspension (ratio to water=1.5:10 by weight). Step 820 is to clean (i.e., degrease) the surface to which catalyst will be applied by using a suitable solvent such as acetone, ethanol and the like. Step 830 is to dry the surface at room temperature to remove solvents. Step 840 is to uniformly spray the aqueous titania suspension over the woody surface to achieve loading density of approximately 1 to 2 g/m². Alternatively, a thickness of approximately 0.6-1.2 micrometer is used for a dry condition. Step 850 is to dry the surface at approximately room temperature or an ambient temperature of approximately 25° to 30° C. Step 860 is to pass the coated surface along with an acrylic or silicone film through a press roller to finalize fixation of the catalyst to the surface. Alternatively, other membranes that are also UV transparent and permeable, and the like can be used in place of the silicone film.

FIG. 9a shows an embodiment of an application of a TiO₂ membrane to residential wood paneling. FIG. 9a depicts a cross section of a wood panel that has been prepared in accordance with the teachings of the invention discussed above. Commercially manufactured piece 910 can be a siding, particle board panel, chipboard, and roof shingles that are subjected to TiO₂ treatment layer 920 in accordance with the teachings of FIG. 8.

Although a section of paneling wood is shown, the invention can also be applied as a surface treatment for other wood products such as cabinet materials. For application to a cabinet material, the surface treatment would further aid in destroying the formaldehyde emissions and other VOC emissions from the embalming treatments that use formaldehyde, as well as destroy the toxic VOCs from the wood itself.

FIG. 9b shows another embodiment of an application of a TiO₂ membrane to a piece of wood furniture such as a chair. In FIG. 9b, a chair includes a wood based body 950 and a cloth/fabric material 960 that has been impregnated with the TiO₂ mixture discussed in relation to FIGS. 8 and 9a. Although a chair is shown, the invention would have applicability to other types of commercial and residential furniture that uses wood components such as but not limited to tables, shelves, and the like.

FIGS. 10A–10C shows a still another embodiment of an application of a TiO₂ membrane to a face mask for masking of airborne toxins. Referring to FIGS. 10a and 10b, a microns thick base support material 1006 is composed of a natural fiber such as 100% cotton. A second layer 1008 also of the same material is impregnated with TiO₂ using the methods previously discussed in this invention. Sandwiched layers 1006 and 1008 are adhered together by glue and the like. Sandwiched layers 1006 and 1008 are attached to ends of an elastic band 1002 such as but not limited to rubber and the like to form a mask 1001. Referring to FIG. 10c, mask 1001 is fitted over a person's face portion 1010. Light 1012 can be natural light such as the sun or alternatively artificial light such as fluorescent light. Light 1012 along with inherent moisture from the ambient air or from the face or mouth of the person 1010 activates the TiO₂ impregnated layer which in turn prevents toxic VOCs such as formaldehyde from reaching the mouth and lungs of a person 1010 wearing mask 1001. Alternatively, support layer 1006 can be a cellulose fiber material such as paper and the like can be in mask 1001. Applications of the face mask can include use by surgery room personnel, health care workers and providers, food preparers and the like.

FIG. 11 illustrates a continuous flow system employed for the photocatalytic oxidation of terpene VOCs in the presence of oxygen or H₂O. The experimental set-up consists of three subsections that include a photo-reactor 1100, reagents preparation system 1105, 1110, 1115, and analytical devices 1160, 1165. Photo-reactor 1100 uses an annular fused silica glass flow reactor having 1025 ml volume. Photo-reactor 1100 was illuminated internally using a 54 Watt, low pressure mercury lamp 1102. The photo-reactor 1100 had a wall temperature maintained at 120 degrees C. Photo-catalyst 1103 was titanium dioxide (Degussa P-25™) deposited on the inside wall of reactor 1100 in the manner described in U.S. Pat. No. 5,246,737. The TiO₂ has a loading density of approximately 0.15 mg/cm². The outlet 1106 of photo-reactor 1100 was attached to an acetone absorber 1130 for collection and analysis of monoterpenes via tee connection 1108. A portion of the reactor output stream was pumped through an automatic injection port 1163 to gas chromatograph 1165 equipped with a flame ionization detector (GC-FD).

A mixture of the three most prevalent terpenic VOCs (α-pinene, β-pinene, limonene) was prepared and used as a feed into the photo-reactor 1100. The feed solution used consisted of 50% by volume α-pinene, 30% by volume β-pinene, and 20% by volume limonene. All three reagents were Aldrich™ chemicals, having a purity of 96% or better. For each experiment, approximately 5 µL of solution was injected into the heated mixing manifold 1105 at a rate of 954.2 µg/min via syringe 1100 and pump 1115, as shown in FIG. 11. The mixing chamber 1105 was packed with glass beads to provide high evaporative surface area and uniform mixing of the feed solution with input airstream from cylinder 1100. Temperatures within the mixing manifold were kept at around 140 degrees C, to allow complete evaporation of these terpenes. Input air entered through two separate heaters 1150 and 1190, each independently metered using flowmeters 1155 and 1185. The air flow was set at 326 standard m³/min, resulting in an input terpene concentration of 516 ppmv into the photoreactor 1100.

Referring to FIG. 11, terpenes were analyzed on a Varian™ gas chromatograph model 3400/Saturn II™ ion trap mass spectrometric (GC-MS) system 1160, equipped with a 15 m×0.243 mm J&W™, 1 µm stationary phase DB-1, glass capillary column.

FIG. 12 depicts the total ion chromatogram (TIC) of the feed solution. FIG. 12 shows the complete separation and analysis of α-pinene, β-pinene and limonene, was complete with great accuracy. FIG. 12 also depicts the manner in which samples of reactor effluent for GC-MS analysis were obtained. This was done by passing reactor exit gas 1127 through the trap 1130 that contained 2.3 ml of acetone, for a period of three minutes. Subsequently, 0.1 µL of this solution was injected onto the GC-MS column at 1158 for the analysis of terpenes. All the light gases such as carbon monoxide (CO), carbon dioxide (CO₂) and methane (CH₄) as well as the volatile compounds such as acetaldehyde (CH₃CHO), acetone (DMK) and others were analyzed using a packed column gas chromatograph (GC) 1165 equipped with a flame ionization detector (FID). As FIG. 11 indicates, a portion of the reactor effluent passes through the GC sample loop via the automatic gas sampling valve 1163 and vacuum pump 1170.

In this example, we demonstrate the effectiveness of the UV-excited titania for total transformation of hazardous compounds of terpene nature, more specifically (α-pinene, β-pinene and limonene). This was done by passing a stream of air contaminated with 516 ppmv of 50% α-pinene, 30% β-pinene and 20% limonene (all by volume) through the photo-reactor 1100 in a manner described above.
Total ion chromatogram (TIC) of the mixture introduced into the photo-reactor 1100 is depicted in FIG. 12. Under a dark condition where no UV radiation is present, reactor effluent analysis depicts the presence of all three monoterpenes as shown in FIG. 13A. Comparing FIGS. 12 and 13A, it is clear that no terpenes conversion occurs in the presence of TiO₂ in the dark. This conclusion is supported by the GC-FID analysis of the reactor effluent depicted in FIG. 14A, which shows no by-product peaks. However, after UV lamp 1102 is turned on, no traces of terpenes could be detected in the reactor effluent, shown in FIG. 14B and FIG. 15, depicting by-product peaks of which the prominent one belongs to the deep oxidation product CO₂. It can be seen that the titania-catalyzed photoproducts of terpenes oxidation are mainly carbon dioxide and water. In order to verify that terpenes do indeed photo-oxidize in the presence of TiO₂ catalyst, the UV lamp was switched off and the reactor effluent was then analyzed for terpenes. Results are depicted in FIG. 13B, indicating the presence of α-pinene, β-pinene, and limonene, in the exit air. Therefore, both titania and light are needed for the destruction of terpenic compounds.

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it has presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

We claim:

1. A face mask for destroying harmful toxic airborne volatile organic compounds (VOCs) such as formaldehyde and terpenes, comprising:
   - a base support material having an upper side and a lower side, the lower side for covering a portion of a face of a wearer;
   - a layer of TiO₂ impregnated material overlying the upper side of the base support material;
   - elastic means for attaching the lower side of the base support material over a portion of a wearer’s face; and
   - means for activating the impregnated material wherein airborne VOCs are destroyed by the impregnated layer.

2. The face mask for destroying harmful toxic VOCs of claim 1, wherein the means for activating the impregnated layer includes:
   - H₂O and light.

3. The face mask for destroying harmful toxic VOCs of claim 2, wherein the H₂O includes a source chosen from at least one of the:
   - mouth, nose and skin of the wearer.

4. The face mask for destroying harmful toxic VOCs of claim 1, wherein the light includes a wavelength of:
   - approximately 400 nm.

5. A method of preventing volatile organic compounds (VOCs) such as formaldehyde and terpenes from being breathed in by a person, comprising covering the nose and mouth of a person with a mask, said mask comprising in combination:
   - a front side and a rear side, the rear side for covering the mouth and nose of a person wearing the mask;
   - a layer of TiO₂ overlying the front side of the mask;
   - water and light are present simultaneously for activating the TiO₂ layer so that airborne VOCs are destroyed by the TiO₂ layer and are not passed to the wearer of the mask.

6. The method of claim 5, wherein the H₂O includes a source chosen from at least one of the:
   - mouth, nose and skin of the wearer.

7. The method of claim 5, wherein the light includes a wavelength of:
   - approximately 400 nm.

8. The method of claim 5, further comprising:
   - attaching the mask to the person with elastic means.
