Neodymium-doped yttrium calcium oxyborate (Nd:YCOB) is the single active gain element for a solid-state laser device capable of achieving both lasing and self-frequency doubling optical effects. A pumping source for optically pumping Nd:YCOB can generate a laser light output of approximately 400 mW at approximately 1060 nm wavelength and a self-frequency doubled output of approximately 60 mW at approximately 530 nm wavelength. Thus, a laser device can be designed that is compact, less expensive and a high-powered source of visible, green laser light.

SELF-FREQUENCY DOUBLED ND-DOPED YCOB LASER

This invention relates to solid-state laser devices, and in particular to a new type of compact, high-power laser with frequency doubling capabilities to generate coherent visible light, and claims priority to U.S. Provisional Patent Application Ser. No. 60/118,301, filed Feb. 2, 1999.

This invention is a Division of patent application Ser. No. 09/495,770 filed on Feb. 1, 2000, now U.S. Pat. No. 6,185,236, by the same assignee as the subject invention, and now allowed.

BACKGROUND AND PRIOR ART

The laser is a device for the generation of coherent, nearly single-wavelength and single-frequency, highly directional electromagnetic radiation emitted somewhere in the range from submillimeter through ultraviolet and x-ray wavelengths. The word laser is an acronym for the most significant feature of laser action: light amplification by stimulated emission of radiation.

There are many different kinds of laser, but they all share a crucial element: each contains material capable of amplifying radiation. This material is called the gain medium, because radiation gains energy passing through it. The physical principle responsible for this amplification is called stimulated emission. It was widely recognized that the laser would represent a scientific and technological step of the greatest magnitude, even before T. H. Maiman constructed the first one in 1960. Laser construction generally requires three components for its operation: (1) an active gain medium with energy levels that can be selectively populated; (2) a pumping process to produce population inversion between some of these energy levels; and usually (3) a resonant electromagnetic cavity structure containing the active gain medium, which serves to store the emitted radiation and provide feedback to maintain the coherence of the electromagnetic field.

In a continuously operating laser, coherent radiation will build up in the cavity to a level set by the decrease in inversion required balancing the stimulated emission process with the cavity and medium losses. The system is said to be lasing, and radiation is emitted in a direction defined by the cavity.

A common approach to converting the laser wavelength to half its value (for example, from 1064 nm to 532 nm), often used to convert infra-red lasers to lasers emitting in the visible part of the spectrum, is to use intra-cavity frequency up conversion (IC). The most common IC approach is to use the intra-cavity frequency doubling (IC). The most common IC approach is to use

The lasers of the present invention use a new crystal material as the active gain medium. The new gain medium is trivalent neodymium-doped yttrium gallium oxyborate referred to herein as Nd:\textsuperscript{3+}:YCr\textsubscript{4}O\textsubscript{4}(BO\textsubscript{3})\textsubscript{4} or Nd:YAB for easier reference. Patent Corporation Treaty (PCT) application number WO 96/26464 reports the growth of calcium gadolinium oxyborate, GdCOB, as the first element of a new family of non-hygroscopic crystals. The abstract for this invention overlooked the self-frequency doubling possibilities of the Nd:YAB crystal. U.S. Pat. No. 5,058,118 disclosed that a single crystal of neodymium doped borate (Nd:YAB) was useful as a self-frequency doubling minilaser generating a 0.532 \mu m (green light) and 0.660 \mu m (red light) laser beam. However, this laser configuration suffers from poor optical quality and self-absorption at 530 nm as disclosed in J. Appl. Phys., Vol. 66, pp. 6052–6058, 1989.

More recently, the approach to generating high power, visible laser light has been to use nonlinear optical crystals to convert near-infrared radiation to the visible portion of the spectrum via second harmonic generation (SHG) (sometimes termed frequency doubling and used interchangeably, herein). This process generates a harmonic wavelength that doubles the frequency of the fundamental wavelength. Since the SHG conversion efficiency is a function of the fundamental laser beam intensity, the nonlinear crystal is often placed inside the cavity of a low-power continuous wave laser to benefit from the higher intracavity fundamental beam intensity. This technique is discussed in U.S. Pat. No. 5,610,934 and U.S. Pat. No. 5,751,751 which provides an example of frequency doubling when neodymium-doped crystals of vanadium oxide (YVO\textsubscript{4}) or (GdVO\textsubscript{4}) are bonded to non-linear crystals of potassium titanyl phosphate (KTP) and potassium titanyl phosphate (KTP) or potassium niobate (KNbO\textsubscript{3}) or KTiOPO\textsubscript{4}.

U.S. Pat. No. 5,802,086 discloses a continuous wave (cw) microlaser with a highly absorbing solid-state gain material, preferably neodymium-doped yttrium orthovanadate (Nd:YVO\textsubscript{4}) that lases at two fundamental wavelengths and
mixers, as an optical parametric oscillator or, when partially substituted by Nd\textsuperscript{3+}, as a frequency doubling laser.
are frequency-mixed in a nonlinear crystal oriented within
the cavity to generate a third wavelength which may be
difficult to generate directly or by frequency doubling.

Popular host crystals including garnet, especially yttrium aluminum garnet (YAG) and yttrium orthovanadate (YVO₃), are discussed in the prior art. However, the search for smaller, less expensive, more powerful, multifunctional lasers continues. The discovery of a new class of laser hosts, the oxyborates, makes possible the combination of linear and nonlinear optical properties in a single active medium. More particularly, the neodymium-doped oxyborate crystal (Nd:YCOB) of the present invention generates a near infrared fundamental light which can be self-frequency doubled to provide a compact, efficient, source of visible green laser light.

**SUMMARY OF THE INVENTION**

The first objective of this invention is to use Nd:YCOB as an active gain medium for a laser.

The second objective of this invention is to provide a self-frequency doubled (SFD) laser using the oxyborate family of crystals as the host crystal.

The third objective of the present invention is to provide a visible light laser that combines the active gain medium and frequency doubler in one single element.

The fourth objective of this invention is to provide a compact efficient source of visible laser light.

A preferred embodiment of the invention provides a neodymium-doped oxyborate crystal (Nd:YCOB) pumped with either tunable or continuous wave (cw) coherent, diode pumped, or titanium:Sapphire laser radiation or near infrared laser. The output is a fundamental light in a range from approximately 760 nanometer (nm) to approximately 840 nm, with highest absorption at approximately 792 nm and approximately 812 nm. The preferred embodiment efficiently generates 530 nm of green laser light.

The optical pumping means which provides energy to the crystal can be selected from one of a coherent or incoherent light pumping source. The incoherent pumping source may be xenon or krypton lamps or light emitting diodes (LED) or laser diodes, which can be of pulsed or continuous wave output. The coherent pumping source may be a laser light source, such as a single laser diode or a matrix laser diode series, which can also be of pulsed or continuous wave output.

Further objects and advantages of this invention will be apparent from the following detailed description of a presently preferred embodiment, which is illustrated in the accompanying drawings.

**BRIEF DESCRIPTION OF THE FIGURES**

**DESCRIPTION OF THE PREFERRED EMBODIMENT**

Before explaining the disclosed embodiments of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangement shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

The Czochralski method, as reported by Qing Ye and Bruce H. T. Chai in the Journal of Crystal Growth 197 (1999) 228–235; “Crystal growth of YCa₄O₅(BO₃)₃ and its orientation” is used to grow the oxyborate crystal for the present invention. When rare-earth elements, such as, neodymium are added during the crystal growing process, the crystal is said to be “doped” with the rare-earth ions. Doping changes the function of the crystal into an active gain medium, since undoped YCOB crystal is a nonlinear optical medium, doping of the crystal with an impurity converts the crystal into a nonlinear optical laser crystal.

When the newly formed crystal is grown from the melt, it is generally in a cylindrical shape called a crystal “boule.” The boule can be cut into a cylindrical rod or other geometric shapes. To make it into a laser crystal it generally requires two flat ends. The flat ends are polished and given an appropriate reflective coating or anti-reflective coating. One end is more reflective than the other; laser light is emitted through the end that is less reflective—the output coupler.

Undoped YCOB has been shown to have a nonlinear coefficient, \( d_{e2} \) of 1.1 pm/V, which is between that of other nonlinear crystals KDP (0.37) and BBO (1.94 pm/V). See J. Appl. Phys. 36, 276 (1997) and W. Koechner, Solid State Laser Engineering, 4th ed. (Springer-Verlag New York, 1996), p. 579.

A concentration of Nd exceeding 5% or more of the doping changes the refractive indices of the crystal; which in turn, changes the optimum angle for phase matching. Nd doping for the present invention is preferably in a range from approximately 2 to approximately 20 weight % of the YCOB crystal, with optimum doping at approximately 10%.

Initial experiments were performed to investigate the potential of Nd:YCOB as a laser medium. A simple hemispherical laser system pumped by a tunable cw Ti:sapphire laser centered either at 792 nm or 812 nm was constructed as shown in FIG. 1. The linear cavity layout 10, consisting of a 5-meter radius of curvature (ROC) high reflective rear mirror, 11 and a 10-cm radius of curvature output coupler, 12. An uncoated 5 mm×5 mm×13 mm long 2% Nd:YCOB crystal, 13, with the Z axis along the laser axis, was placed next to the high reflector, 11. The pump laser polarization was rotated for maximum absorption (along the Z-axis) in the crystal and focused into the crystal with an 8.8-cm plano/convex lens, 14, through the rear mirror which was approximately 82% transparent at 792 nm and 812 nm. The tunable Ti:sapphire pumping source 15, passed through the Faraday isolator 16, and traveled through the half-wave plate, 17. The half-wave plate can be used to rotate the polarization of the pump radiation.

The required optical components for the solid state laser device of this invention are the active gain medium and a...
3b. Wavelengths were measured for both 2% Nd:YCOB and 5% Nd:YCOB. It is theoretically possible for Nd-doping to be in a range up to 50 weight%; however, it is most preferred that doping be in a range from 2 to 10 weight % of the YCOB crystal. The inventors have discovered that Nd-doping concentration of approximately 10 weight % is most efficient; above 10% quenching and degradation of the crystal starts. Preferably, the YCOB crystal can be anti-reflective coated. The output power at both fundamental and self-frequency doubled laser wavelengths were measured for 0, 1% and 2% output coupling.

FIG. 2 shows the fundamental output power for 2% output coupling versus absorbed pump power in a 2% Nd:YCOB laser. The minimum pump threshold for lasing at 530 nm was determined to be 97 mW for the lowest transmission output coupler. Slope efficiencies of 44% with fundamental output powers exceeding 400 mW for 1 W of absorbed pump power was observed for 2% output coupling. Green self-frequency doubled output powers of over 0.7 mW were measured for 1 W of absorbed pump power in this experimental laser system.

In another embodiment, efficient self-frequency doubling was demonstrated utilizing a 3 mmx3 mmx5 mm rotated Z-plate of 5% Nd:YCOB. Utilizing the cavity design identical to the linear cavity in FIG. 1, various pumping means were employed. The measurements shown in FIG. 3 confirm the potential efficiency of a 5% Nd:YCOB laser system when pumped by Ti:Sapphire radiation (3a) and diode laser (3b).

To maximize the SFD output, the output coupler was highly reflecting at 1060 nm (R>99.9%) and highly transmitting (T>94%) at 530 nm. The SFD output was optimized by adjusting the angle and hence phase matching of the crystal, by varying the mode size in the crystal, and changing the cavity length. The SFD power as a function of absorbed Ti:Sapphire pump power for a laser having an active medium of 5% Nd:YCOB is shown in FIG. 3a. Nearly 60 mW of 530 nm laser light was obtained with 900 mW of pump power absorbed in the crystal. The laser threshold for SFD output was only 23 mW of power absorbed in the crystal. No additional elements were inserted into the cavity to narrow the linewidth of the laser.

Utilizing the same configuration as above, but with single diode-pumping, 62 mW of 530 nm SFD light was generated for pump power up to 860 mW absorbed power. See FIG. 3b.

Properties, orientation and structure of the host crystal were examined. YCOB has a monoclinic crystal structure belonging to the space group Cm (point group m).

The optical indicatrix axes (X, Y and Z) are defined relative to the crystallographic axes (a, b and c) and planes as shown in FIG. 4, by adopting the traditional refractive index convention n_a, n_b, n_c. The b and Y axes are collinear but opposite in direction, which is denoted by the cross and dot signs. The crystal was cut with polished faces aligned at an angle of approximately 34° to the X-axis as shown in FIG. 5. The crystal surfaces were coated with an anti-reflective coating that had less than 1% reflection at 1060, 530 and 812 nm. The crystal absorbed approximately 80% of the pump light. Measurements of the polarized absorption and emission spectra of 5% Nd:YCOB for light polarized parallel to the X, Y, and Z axes were taken. The results are shown in FIGS. 6 and 7; confirming that the strongest absorption and emission of light occurs for light polarized parallel to the Z-axis. Referring to FIG. 6, the several strong absorption peaks in the vicinity of 800 nm make this material attractive for laser diode pumping. It is again noted that with the addition of diode pumping, the Nd:YCOB laser provides a type of compact, high-power visible green laser light source.

From the foregoing experiments it was observed that diode pumped self-frequency doubling in a Nd:YCOB laser system can be demonstrated with a dichroic mirror coated directly on the face of one of the polished crystal surfaces. SFD laser emission has been observed with modest pump powers from a low brightness laser diode. It is shown that the new material, Nd:YCOB, is a promising laser crystal for development of the next generation of compact, diode-pumped, solid-state, visible laser systems.

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it is presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

We claim:

1. A crystal orientation for self-frequency doubling laser action, comprising:

   a crystal having crystallographic axes (a, b, c) with an optical indicatrix axes (x, y, z) relative to the crystallographic axes, where b and x are collinear and opposite in direction to one another, the crystal being cut at an angle of approximately 34 degrees to the x axis, and the crystal absorbing up to approximately 80% of a pumped laser light source, wherein the crystal produces a self-frequency doubled beam of green laser light.

2. The crystal orientation of claim 1, wherein the crystal further includes the a axis being approximately 23 degrees from the Z axis and the c axis being approximately 12 degrees from the X axis.

3. The crystal orientation of claim 1, wherein the pumped laser light source is chosen from at least one of: a xenon lamp, a krypton lamp, an array of laser diodes, and a semi-conductor diode laser.

4. The crystal orientation of claim 1, wherein the pumped light source is tuned to a wavelength range of approximately 760 nm to 840 nm.

5. The crystal orientation of claim 1, wherein the crystal further includes an anti-reflective coating at a range chosen from at least one of: approximately 520 to approximately 530 nm, approximately 760 to approximately 840 nm, and approximately 1040 to approximately 1060 nm.

6. The crystal orientation of claim 1, wherein the crystal includes: Nd:YCOB crystal.

7. A method of orienting a crystal for self-frequency doubling laser action, comprising the steps of:

   forming a crystal having crystallographic axes (a, b, c) with an optical indicatrix axes (x, y, z) relative to the crystallographic axes, where b and x are collinear and opposite in direction to one another,
cutting the crystal at an angle of approximately 34 degrees to a x axis; and generating a fundamental beam that is self-frequency doubled to produce green laser light.

8. The method of claim 7, wherein the crystal further includes the a axis being approximately 23 degrees from the Z axes and the c axis being approximately 12 degrees from the X axis.

9. The method of claim 7, further comprising the step of: tuning the pumped light source to a wavelength range to approximately 760 to approximately 840 nm.

10. The method of claim 7, further comprising the step of: coating the crystal with an anti-reflective coating at a range chosen from at least one of: approximately 520 to approximately 530 nm, approximately 760 to approximately 840 nm, and approximately 1040 to approximately 1060 nm.

11. The method of claim 7, wherein the crystal includes: Nd:YCOB crystal.
