Disclosed herein are novel methods for screening for compounds useful in treating or preventing tuberculosis. In exemplary embodiments, screening methods are based on the implementation or manipulation of triacylglycerol hydrolase like polypeptides or polynucleotides encoding the same. The methods are useful in identifying agents active against TB infection.

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is related to U.S. Provisional Patent No. 60/748,284, filed Dec. 7, 2005, which is incorporated herein by reference. Priority is claimed under 35 USC § 119.

GOVERNMENT SUPPORT

This invention was made through support from the NIH, Grant Nos. AI46582 and AI35272. The government may have certain rights in this invention.

BACKGROUND

Tuberculosis (TB) has been a major health problem for most of recorded history and Mycobacterium tuberculosis remains one of the world’s most significant pathogens. Responsible for millions of new cases of tuberculosis annually (see e.g. Pablo-Mendez et al., (1998) New Engl. J. Med. 338, 1641-1649), it is the leading cause of death from a single infectious agent. While the incidence of the disease declined in parallel with advancing standards of living since at least the mid-nineteenth century, in spite of the efforts of numerous health organizations worldwide, the eradication of tuberculosis has never been achieved, nor is imminent.

TB is acquired by the respiratory route; actively infected individuals spread this infection efficiently by coughing or sneezing “droplet nuclei” which contain viable bacilli. Overcrowded living conditions and shared air spaces are especially conducive to the spread of TB, underlying the increase in instances that have been observed in the U.S. in prison inmates and among the homeless in larger cities.

Medical experts estimate that about 10 million Americans are infected with TB bacteria, and about 10 percent of these people will develop active TB in their lifetime. However, TB is an increasing worldwide problem, especially in Africa. It is estimated that, worldwide, about one billion people will become newly infected, over 150 million people will contract active TB, and 36 million people will die between now and 2020 unless TB control is improved.

The emergence of drug-resistant strains of Mycobacterium tuberculosis poses serious threats to the control of this disease due to the complex nature of second-line drug treatment (WHO Report. (2004) WHO/HTM/TB/2004.343). Upon infection the bacterium goes through an initial replication phase inside the alveolar macrophages after which it enters a non-replicative, drug-resistant state of dormancy. This state of dormancy is probably induced by the environmental stress exerted upon the pathogen by the host’s immune response. The bacterium is able to survive in this dormant state for decades until the host’s immune system is weakened when it reactivates and causes the infectious disease (Donnenberg, Jr., A. M., and Rook G. A. W. (1994) In Pathogenesis: Protection and Control, Bloom, B. R., (Ed.) American Society of Microbiology, Washington D.C.).

If an individual has TB disease, i.e., has active TB, the individual typically is administered a combination of several drugs. It is very important, however, that the individual continue a correct treatment regimen for the full length of the treatment. If the drugs are taken incorrectly, or stopped, the individual can suffer a relapse and will be able to infect others with TB.

When an individual becomes sick with TB a second time, the TB infection may be more difficult to treat because the TB bacteria have become drug resistant, i.e., TB bacteria in the body are unaffected by some drugs used to treat TB. Multidrug-resistant tuberculosis (MDR TB) is a very dangerous form of tuberculosis. In particular, some TB bacteria become resistant to the effects of various anti-TB drugs, and these resistant TB bacteria then can cause TB disease. Like regular TB, MDR TB can be spread to others.

To avoid drug resistance in the treatment of TB, a four-drug regimen, i.e., isoniazid, rifampin, pyrazinamide, and streptomycin, is administered to TB patients. Aminoglycosides, such as streptomycin, are important anti-TB agents, but their utility is restricted by the requirement of parenteral administration, which is inconvenient and leads to poor patient compliance. It is theorized that poor patient compliance can lead to the development of drug resistance, and it appears that the frequency of streptomycin resistance among anti-TB drugs is surpassed only by isoniazid.

In view of the above, an urgent need exists for new anti-TB agents useful in an effective treatment regimen for both the active and latent TB, and that effectively treat TB caused by multidrug resistant (MDR) strains of bacteria. Therefore, it would be advantageous to provide compounds and compositions for administration to an individual in the treatment of tuberculosis.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1: Triacylglycerol (TG) utilization by M. tuberculosis wild type and lipY mutant cells under nutrient starvation condition. (A) Autoradiogram and (B) dichromate/sulfuric acid staining of lipids showing utilization of TG by wild type M. tuberculosis in PBS medium. After 12 days of hypoxic growth, cells were incubated with 1 μCi of 14C-o-leic acid for 1 hr and the cells were washed with PBS prior to 6 hr incubation in same media. (C) Dichromate/sulfuric acid staining of lipids showing utilization of TG accumulated during 12 days of hypoxic growth of M. tuberculosis (wild type) and lipY mutant cells at 0 hr and by 6 hr incubation in PBS and nutrient rich (7H9) media. Lipids were separated on Silica gel TLC using n-hexane:diethyl ether (9:1, v/v) as developing solvent. In panel A, autoradiogram is shown from a typical experiment and the incorporation values of 14C into TG is shown as a percentage of the total 14C administered. In panel B and C, charred TLC chromatograms are shown from a typical experiment and the intensity of the TG band was determined in arbitrary units by the Alphaimager 2200 Gel Doc system. On top of each panel, the values are given as SEM of three independent measurements.

FIG. 2: RT-PCR assessment of the induction of lip genes upon starvation (A) and estimation of the potential contribution to TG hydrolysis (B). M. tuberculosis H37Rv was incubated in PBS or in 7H9 medium for 6 hours after TG accumulation by hypoxic growth for 12 days. Transcript levels of lips are
shown as a fraction of 23S RNA transcripts (mean±SD from three independent experiments). The methods used for quantitation and experimental details are given in Experimental Procedures. In B, the potential relative contribution of each lip enzyme product to the total lipase activity was estimated by multiplying transcript level with the lipase activity of each gene product expressed in E. coli.

FIG. 3: Generation of a lipY deficient mutant of M. tuberculosis. (A) Genomic organization of lipY (Rv3097c). (B) Schematic representation of the disruption construct for lipY. A hatched region with grey flanks depicts the genome sequence of lipY and its flanking regions used to make the disruption construct. Primer pairs A/B and C/D were used to amplify the 5'- and 3'-flanks of the disruption construct. The part of the lipY gene (upward diagonal hatch) replaced with 15 nucleotides from the part of the lipY gene (upward diagonal hatch) replaced with 15 nucleotides

FIG. 4: SDS-PAGE analysis of the expression and purification of LIPY. His-tagged LIPY was expressed in E. coli BL21 cells, solubilized from the 16,000g pellet from cell lysate and purified by co-purification by cobalt affinity chromatography (TALON) as described in Experimental Procedures. Protein samples were loaded on a 12% SDS-polyacrylamide gel under reducing conditions. Lane 1, Benchmark prestained molecular weight markers (Invitrogen); lane 2, 16,000g supernatant from solubilized inclusion bodies; lane 3, flow-through fraction from TALON resin; lanes 4-5, 10 mM imidazole wash; lanes 6-9, 150 mM imidazole eluted fractions.

FIG. 5: Characterization of triolein hydrolase activity of purified LIPY. (A) Time-course of [14C]triolein hydrolysis at pH 8.0 was determined using 8 µg of purified LIPY protein per assay. (B) Protein concentration dependence of TG hydrolysis (incubation time, 2 h) C) substrate concentration dependence of activity (incubation time, 2 h). D) Effect of pH on lipase activity. LIPY was incubated for 1.5 min at room temperature in 0.1 M citrate-phosphate buffer pH 6.0 or 0.1 M potassium phosphate buffer pH 7.0 or 0.1 M Tris-HCl pH 7.5; pH 8.0; pH 8.5; pH 9.0 or 0.1 M glycine-NaOH buffer pH 10.0 prior to the assay. Values are mean±SD from three replicates.

FIG. 6: Effect of E-600 (A), and PMSF (B), and temperature on TG hydrolysis by LIPY. LIPY was incubated with indicated concentration of inhibitor for 1.5 min at room temperature prior to assay at 37°C. In C, LIPY was incubated as indicated temperature for 15 min prior to assay. Values are mean±SD from three separate experiments.

FIG. 7: Effect of detergents on LIPY activity. Purified LIPY was pre-incubated with the indicated concentrations of SDS (A), Triton X-100 (B) or Tween-20 (C) for 15 min at room temperature prior to assay. Activity relative to control is given as mean±SD from three replicates.

FIG. 8: Structure-based alignment of the conserved domains of LIPY with lipases from the HSL family. The multiple sequence alignment produced by ClustalW and the output was manually adjusted for optimal alignment. The sequences selected for alignment with LIPY (SEQ ID NO: 69) are A. fulgidus carboxylesterase (GI 17943077; SEQ ID NO: 70), Acinetobacter esterase (GI 34559428; SEQ ID NO: 71)), Human HSL (GI 21328445; SEQ ID NO: 72), Pseudomonas B11-1 lipase (GI 2853612; SEQ ID NO: 73), B. subtilis brefeldin A esterase (GI 414722; SEQ ID NO: 74), M. tuberculosis CDC1551 esterase (GI 15840511; SEQ ID NO: 75), M. tuberculosis CDC1551 PE family protein (GI 15842668; SEQ ID NO: 76), R. solanacearum putative esterase/lipase (GI 17545158; SEQ ID NO: 77), and S. aureus hypothetical protein (GI 15928114; SEQ ID NO: 78). Black shading indicates residues conserved in seven or more aligned sequences and shades of gray are used to indicate residues conserved in a few sequences. ▲ amino acids belonging to the catalytic triad. The ClustalW program was accessed from the European Bioinformatics Institute website www.ebi.ac.uk.

DETAILED DESCRIPTION

The ability of Mycobacterium tuberculosis to go into a latent/dormant state and survive under such conditions for decades makes TB control extremely difficult. Developing drugs targeted at the ability of the pathogen to survive under such latent conditions is one way to help fight against latent TB. The invention is based, in part, on the inventors discovery of a novel TG gene (Rv3097c) encoding an enzyme required for Mycobacterium tuberculosis to process energy in order to enter, survive, or exit the dormancy (or latent) period. The gene sequence is provided as SEQ ID NO: 1. The inventors believe that triacylglycerol (TG) could be used as an energy source by M. tuberculosis during the dormancy period, thus its synthesis or its metabolism could be an ideal drug target against latent TB.

Accordingly, the inventors have screened putative lipase/esterase gene products from M. tuberculosis for long-chain TG hydrolyase activity and have discovered that the Rv3097c gene product, is active as a true lipase. LIPY (PE-PGRS63), which is a member of PE-PGRS family, is a lipase belonging to the hormone-sensitive lipase (HSL) family and hydrolyzes long-chain TG with high specific activity. The inventors have also found that lipY is upregulated to a much higher level than the transcripts of other lipase/esterase-like genes when mycobacteria that accumulated TG during an in vitro dormancy-like state were subjected to TG utilizing conditions indicating that this lipase plays a role in the utilization of TG for survival through dormancy. The inventors discover herein that the ability to hydrolyze stored TG was drastically diminished in a lipY disrupted mutant (Δ-lipY).

Thus, one embodiment of the subject invention pertains to a method of screening for therapeutic agents useful in the treatment of Mycobacterium tuberculosis infection in a mammal comprising the steps of i) contacting a test compound with a M. tuberculosis TG hydrolyase (MTTGH) polypeptide, ii) detecting binding of said test compound to said MTTGH polypeptide.

Another embodiment the subject invention is directed to a method of screening for therapeutic agents useful in the treatment of Mycobacterium tuberculosis infection in a mammal comprising the steps of i) determining the activity of the MTTGH polypeptide at a certain concentration of a test compound or in the absence of said test compound, ii) determining the activity of said polypeptide at a different concentration of said test compound. These and other embodiments will be described in further detail herein.

1. Screening Methods

The invention provides assays for screening test compounds which bind to or modulate the activity of an MTTGH polypeptide or bind to and inhibit or affect expression of an MTTGH polypeptide. A test compound preferably binds
to an MTTGH polypeptide. More preferably, a test compound decreases or increases MTTGH activity by at least about 10, preferably about 50, more preferably about 75, 90, or 100% relative to the absence of the test compound.

1.1. Test Compounds

Test compounds relate to agents that potentially have therapeutic activity, i.e., bind to or modulate the activity of an MTTGH polypeptide or bind to or affect expression of an MTTGH polynucleotide. Test compounds can be pharmacologic agents already known in the art or can be compounds previously unknown to have any pharmacological activity. The compounds can be naturally occurring or designed in the laboratory. They can be isolated or isolated from microorganisms, animals, or plants, and can be produced recombinantly, or synthesized by chemical methods known in the art. If desired, test compounds can be obtained using any of the numerous combinatorial library methods known in the art, including but not limited to, biological libraries, spatially addressable parallel solid phase or solution phase libraries, synthetic library methods requiring deconvolution, the "one-bead-one-compound" library method, and synthetic library methods using affinity chromatography selection. The biological library approach is limited to polypeptide libraries, while the other four approaches are applicable to polypeptide, non-peptide oligomers, or small molecule libraries of compounds. See Lam, Anticancer Drug Des. 12, 145, 1997.

1.2. High Throughput Screening

Test compounds can be screened for the ability to bind to and inhibit MTTGH polypeptides or polynucleotides or to affect MTTGH activity or MTTGH gene expression using high throughput screening. Using high throughput screening, many discrete compounds can be tested in parallel so that large numbers of test compounds can be quickly screened. The most widely established techniques utilize 96-well microtiter plates. The wells of the microtiter plates typically require assay volumes that range from 50 to 500 µL. In addition to the plates, many instruments, materials, pipetters, robotics, plate washers, and plate readers are commercially available to fit the 96-well format.

Alternatively, "free format assays," or assays that have no physical barrier between samples, can be used.

1.3. Binding Assays

For binding assays, the test compound is preferably, but not necessarily, a small molecule which binds to and occupies, for microtiter plates. The wells of the microtiter plates typically require assay volumes that range from 50 to 500 µL. In addition to the plates, many instruments, materials, pipetters, robotics, plate washers, and plate readers are commercially available to fit the 96-well format.

Alternatively, "free format assays," or assays that have no physical barrier between samples, can be used.

Those skilled in the art equipped with teachings herein will appreciate that there are multiple conventional methods of detecting binding of a test compound. For example, binding of a test compound to an MTTGH polypeptide can be determined without labeling either of the interactants. A microphysiometer can be used to detect binding of a test compound with an MTTGH polypeptide. A microphysiometer (e.g., CYTOSENSOR™) is an analytical instrument that measures the rate at which a cell acidifies its environment using a light-addressable potentiometric sensor (LAPS). Changes in this acidification rate can be used as an indicator of the interaction between a test compound and an MTTGH polypeptide (McConnell et al., Science 257, 19061912, 1992).

In another alternative example, determining the ability of a test compound to bind to an MTTGH polypeptide can be accomplished using a technology such as real-time Biomolecular Interaction Analysis (BIA) (Sjolander & Urbaniczky, Anal Chem. 63, 23382345, 1991, and Szabo et al.,Curr. Opin. Struct. Biol. 5, 699705, 1995). BIA is a technology for studying biospecific interactions in real time, without labeling any of the interactants (e.g., BIAcore™). Changes in the light phenomenon surface plasmon resonance (SPR) can be used as an indication of real-time reactions between biological molecules.

In yet another aspect of the invention, an MTTGH polypeptide can be used as a "bait protein" in a two-hybrid assay or three-hybrid assay (see, e.g., U.S. Pat. No. 5,283,317; Zervos et al., Cell 72, 223232, 1993; Madura et al., J. Biol. Chem. 268, 1204612054, 1993; Bartel et al., Biotechniques 14, 920929, 1993; Iwabuchi et al., Oncogene 8, 16931696, 1993; and Brent WO9410300), to identify other proteins which bind to or interact with the MTTGH polypeptide and modulate its activity.

In many screening embodiments, it may be desirable to immobilize either the MTTGH polypeptide (or polynucleotide) or the test compound to facilitate separation of bound from unbound forms of one or both of the interactants, as well as to accommodate automation of the assay. Thus, either the MTTGH polypeptide (or polynucleotide) or the test compound can be bound to a solid support. Suitable solid supports include, but are not limited to, glass or plastic slides, tissue culture plates, microtiter plates, tubes, silicon chips, or particles such as beads (including, but not limited to, latex, polystyrene, or glass beads). Any method known in the art can be used to attach the MTTGH polypeptide (or polynucleotide) or test compound to a solid support, including use of covalent and non-covalent linkages, passive absorption, or pairs of binding moieties attached respectively to the polypeptide (or polynucleotide) or test compound and the solid support. Test compounds are preferably bound to the solid support in an array, so that the location of individual test compounds can be tracked. Binding of a test compound to a MTTGH polypeptide (or polynucleotide) can be accomplished in any vessel suitable for containing the reactants. Examples of such vessels include microtiter plates, test tubes, and microcentrifuge tubes.

In a specific embodiment, the MTTGH polypeptide may be a fusion protein comprising a domain that allows the MTTGH polypeptide to be bound to a solid support. For example, glutathione S-transferase fusion proteins can be adsorbed onto glutathione sepharose beads (Sigma Chemical, St. Louis, Mo.) or glutathione derivatized microtiter plates, which are then combined with the test compound or the test compound and the nonadsorbed MTTGH polypeptide; the mixture is then incubated under conditions conducive to complex formation (e.g., at physiological conditions for salt and pH). Following incubation, the beads or microtiter plate wells
are washed to remove any unbound components. Binding of the interactants can be determined either directly or indirectly, as described above. Alternatively, the complexes can be dissociated from the solid support before binding is determined.

Other techniques for immobilizing proteins or nucleic acids on a solid support also can be used in the screening assays of the invention. For example, either a MTGH polypeptide (or polynucleotide) or a test compound can be immobilized utilizing conjugation of biotin and streptavidin. Biotinylated MTGH polypeptides (or polynucleotides) or test compounds can be prepared from biotin-NHS (N-hydroxysuccinimide) using techniques well known in the art (e.g., biotinylation kit, Pierce Chemicals, Rockford, Ill.) and immobilized in the wells of streptavidin-coated 96 well plates (Pierce Chemical). Alternatively, antibodies which specifically bind to a MTGH polypeptide, polynucleotide, or a test compound, but which do not interfere with a desired binding site, such as the active site of the MTGH polypeptide, can be derivatized to the wells of the plate. Unbound target or protein can be trapped in the wells by antibody conjugation.

Methods for detecting such complexes, in addition to those described above for the GST-immobilized complexes, include immunodetection of complexes using antibodies which specifically bind to the MTGH polypeptide or test compound, enzyme-linked assays which rely on detecting an activity of the MTGH polypeptide, and SDS gel electrophoresis under non-reducing conditions.

Screening for test compounds which bind to a MTGH polypeptide or polynucleotide also can be carried out in an intact cell. Any cell which comprises a MTGH polypeptide or polynucleotide can be used in a cell-based assay system. A MTGH polynucleotide can be naturally occurring in the cell or can be introduced using techniques such as those described above. Binding of the test compound to a MTGH polypeptide or polynucleotide is determined as described above.

1.4. Enzyme Assays

Test compounds can be tested for the ability to increase or decrease the TGS activity of a MTGH polypeptide. TGS activity can be measured, for example, by adapting techniques such as that described in U.S. Pat. No. 4,529,693 (see Example 2). Enzyme assays can be carried out after contacting either a purified MTGH polypeptide, a cell membrane preparation, or an intact cell with a test compound. A test compound which decreases TGS activity of a MTGH polypeptide by at least about 10, preferably about 50, more preferably about 75, 90, or 100% is identified as a potential therapeutic agent for decreasing MTGH activity. A test compound which increases TGS MTGH polypeptide by at least about 10, preferably about 50, more preferably about 75, 90, or 100% is identified as a potential therapeutic agent for increasing TGS activity.

1.5. Gene Expression

In another embodiment, test compounds which increase or decrease MTGH gene expression are identified. An MTGH polynucleotide is contacted with a test compound, and the expression of an RNA or polypeptide product of the MTGH polynucleotide is determined. The level of expression of appropriate mRNA or polypeptide in the presence of the test compound is compared to the level of expression of mRNA or polypeptide in the absence of the test compound. The test compound can then be identified as a modulator of expression based on this comparison. For example, when expression of mRNA or polypeptide is greater in the presence of the test compound than in its absence, the test compound is identified as a stimulator or enhancer of the mRNA or polypeptide expression. Alternatively, when expression of the mRNA or polypeptide is less in the presence of the test compound than in its absence, the test compound is identified as an inhibitor of the mRNA or polypeptide expression.

The level of MTGH mRNA or polypeptide expression in the cells can be determined by methods well known in the art for detecting mRNA or polypeptide. Either qualitative or quantitative methods can be used. The presence of polypeptide products of an MTGH polynucleotide can be determined, for example, using a variety of techniques known in the art, including immunochemical methods such as radioimmunoassay, Western blotting, and immunohistochemistry. Alternatively, polypeptide synthesis can be determined in vivo, in a cell culture, or in an in vitro translation system by detecting incorporation of labeled amino acids into a MTGH polypeptide.

Such screening can be carried out either in a cell-free assay system or in an intact cell. Any cell which expresses a MTGH polynucleotide can be used in a cell-based assay system. The MTGH polynucleotide can be naturally occurring in the cell or can be introduced using techniques such as those described above. Either a primary culture or an established cell line, such as CHO or human embryonic kidney 293 cells, can be used.

2. Pharmaceutical Compositions

The invention also pertains to pharmaceutical compositions comprising one or more therapeutic agents that are identified by screening methods that utilize MTGH polypeptides and/or polynucleotides. Therapeutic agent(s) can be administered to a patient to achieve a therapeutic effect, i.e., useful in treatment of TB. Pharmaceutical compositions of the invention can comprise, for example, therapeutic agents identified by a screening method embodiment described herein, which are identified by their ability to bind to or affect activity of MTGH polypeptides, or bind to and/or affect expression MTGH polynucleotides. The compositions can be administered alone or in combination with at least one other agent, such as stabilizing compound, which can be administered in any sterile, biocompatible pharmaceutical carrier, including, but not limited to, saline, buffered saline, dextrose, and water. The compositions can be administered to a patient alone, or in combination with other agents, drugs or hormones. In addition to the active ingredients, these pharmaceutical compositions can contain suitable pharmaceutically acceptable carriers comprising excipients and auxiliaries which facilitate processing of the active compounds into preparations which can be used pharmaceutically. Pharmaceutical compositions of the invention can be administered by any number of routes including, but not limited to, oral, intravenous, intramuscular, intra-arterial, intramedullary, intrathecal, intraventricular, transdermal, subcutaneous, intraperitoneal, intranasal, parenteral, topical, sublingual, or rectal means. Pharmaceutical compositions for oral administration can be formulated using pharmaceutically acceptable carriers well known in the art in dosages suitable for oral administration. Such carriers enable the pharmaceutical compositions to be formulated as tablets, pills, dragees, capsules, liquids, gels, syrups, slurries, suspensions, and the like, for ingestion by the patient.

Further details on techniques for formulation and administration can be found in the latest edition of REMINGTON'S PHARMACEUTICAL SCIENCES (Maack Publishing Co., Easton, Pa., which is incorporated herein by reference). After pharmaceutical compositions have been prepared, they can be placed in an appropriate container and labeled for treat-
ment of an indicated condition. Such labeling would include amount, frequency, and method of administration.

This invention further pertains to the use of novel agents identified by the screening assays described above. Accordingly, it is within the scope of this invention to use a therapeutic agent identified as described herein in an appropriate animal model. For example, an agent identified as described herein (for example, but not limited to, a modulating agent, an antisense nucleic acid molecule, a specific antibody, ribozyme, or a MTTGH polypeptide binding molecule) can be used in an animal model to determine the efficacy, toxicity, or side effects of treatment with such an agent. Furthermore, this invention pertains to uses of novel agents identified by the above described screening assays for treatments as described herein.

Those skilled in the art will appreciate that numerous delivery mechanisms are available for delivering a therapeutic agent to an area of need. By way of example, the agent may be delivered using a liposome as the delivery vehicle. Preferably, the liposome is stable in the animal into which it has been administered for at least about 30 minutes, more preferably for at least about 1 hour, and even more preferably for at least about 24 hours. A liposome comprises a lipid composition that is capable of targeting a reagent, particularly a polynucleotide, to a particular site in an animal, such as a human. A liposome useful in the present invention comprises a lipid composition that is capable of fusing with the plasma membrane of the targeted cell to deliver its contents to the cell. Preferably, the transfection efficiency of a liposome is about 0.5 µg of DNA per 16 nmole of liposome delivered to about 10^6 cells, more preferably about 1.0 µg of DNA per 16 nmole of liposome delivered to about 10^6 cells, and even more preferably about 2.0 µg of DNA per 16 nmole of liposome delivered to about 10^6 cells. Preferably, a liposome is between about 100 and 500 nm, more preferably between about 150 and 450 nm, and even more preferably between about 200 and 400 nm in diameter.

Suitable liposomes for use in the present invention include those liposomes standardly used in, for example, gene delivery methods known to those of skill in the art. More preferred liposomes include liposomes having a polycationic lipid composition and/or liposomes having a cholesterol backbone conjugated to polyethylene glycol. Optionally, a liposome comprises a compound capable of targeting the liposome to a particular cell type, such as a cell-specific ligand exposed on the outer surface of the liposome. Complexing a liposome with a reagent such as an antisense oligonucleotide or ribozyme can be achieved using methods which are standard in the art (see, for example, U.S. Pat. No. 5,705,151). Preferably, from about 0.1 µg to about 10 µg of polynucleotide is combined with about 8 nmol of liposomes, more preferably from about 0.5 µg to about 5 µg of polynucleotides are combined with about 8 nmol liposomes, and even more preferably about 1.0 µg of polynucleotides is combined with about 8 nmol liposomes.

In another embodiment, antibodies can be delivered to specific tissues in vivo using receptor-mediated targeted delivery. Receptor-mediated DNA delivery techniques are generally available to practitioners in the art, such as hybridization of nucleotide probes to MTTGH-specific mRNA, quantitative RT-PCR, immunologic detection of an MTTGH polypeptide, or measurement of MTTGH activity.

In any of the embodiments described above, any of the pharmaceutical compositions of the invention can be administered in combination with other appropriate therapeutic agents. Selection of the appropriate agents for use in combination therapy can be made by one of ordinary skill in the art, according to conventional pharmaceutical principles. The combination of therapeutic agents can act synergistically to effect the treatment or prevention of the various disorders described above. Using this approach, one may be able to achieve therapeutic efficacy with lower dosages of each agent, thus reducing the potential for adverse side effects. Any of the therapeutic methods described above can be applied to any subject in need of such therapy.

3. Polypeptides

_**M. tuberculosis** TG storage (MTTGH) polypeptides according to the invention comprise at least 12, 15, 25, 50, 75, 100, 125, 150, 175, 200, 225, 250 or 265 contiguous amino acids selected from the amino acid sequence shown in SEQ ID NO: 2, or a biologically active variant thereof, as defined below. A MTTGH polypeptide of the invention therefore can be a portion of an MTTGH protein, a full-length MTTGH protein, or a fusion protein comprising all or a portion of MTTGH protein.
3.1 Biologically Active Variants
MTTGH polypeptide variants which are biologically active, i.e., confer an ability by M. tuberculosis to store or process TG, also are considered MTTGH polypeptides for purposes of this application. Preferably, naturally or non-naturally occurring MTTGH polypeptide variants have amino acid sequences which are at least about 55, 60, 65, or 70, preferably about 75, 80, 85, 90, 96, 98, or 98% identical to the amino acid sequence shown in SEQ ID NO: 2 or a fragment thereof. Percent identity between a putative MTTGH polypeptide variant and an amino acid sequence of SEQ ID NO: 2 is determined using the Blast2 alignment program (Blossum62, Expect 10, standard genetic codes).

Variations in percent identity can be due, for example, to amino acid substitutions, insertions, or deletions. Amino acid substitutions are defined as one for one amino acid replacements. They are conservative in nature when the substituted amino acid has similar structural and/or chemical properties. Examples of conservative replacements are substitution of a leucine with an isoleucine or valine, an aspartate with a glutamate, or a threonine with a serine.

Amino acid insertions or deletions are changes to or within an amino acid sequence. They typically fall in the range of about 1 to 5 amino acids. Guidance in determining which amino acid residues can be substituted, inserted, or deleted may be found in the art. Without abolishing biological or immunological activity of an MTTGH polypeptide can be found using computer programs well known in the art, such as DNA STAR software. Whether an amino acid change results in a biologically active MTTGH polypeptide can readily be determined by assaying for MTTGH activity, as described for example, in the specific Examples, below.

3.2 Fusion Proteins
In some embodiments of the invention, it is useful to create fusion proteins. By way of example, fusion proteins are useful for generating antibodies against MTTGH polypeptide amino acid sequences and for use in various assay systems. For example, fusion proteins can be used to identify proteins which interact with portions of an MTTGH polypeptide. Protein affinity chromatography or library-based assays for protein—protein interactions, such as the yeast two-hybrid or phage display systems, can be used for this purpose. Such methods are well known in the art and also can be used as drug screens.

A MTTGH polypeptide fusion protein comprises two polypeptide segments fused together by means of a peptide bond. For example, the first polypeptide segment can comprise at least 12, 15, 25, 50, 75, 100, 125, 150, 175, 200, 225, or 250 contiguous amino acids of SEQ ID NO: 2 or of a biologically active variant, such as those described above. The first polypeptide segment also can comprise full-length MTTGH protein.

The second polypeptide segment can be a full-length protein or a protein fragment. Proteins commonly used in fusion protein construction include galactosidase, glucuronidase, green fluorescent protein (GFP), autoflourescent proteins, including blue fluorescent protein (BFP), glutathione-S-transferase (GST), luciferase, horseradish peroxidase (HRP), and chloramphenicol acetyltransferase (CAT). Additionally, epitope tags are used in fusion protein constructions, including histidine (His) tags, FLAG tags, influenza hemagglutinin (HA) tags, Myc tags, VSV-G tags, and thioredoxin (Trx) tags. Other fusion constructions can include maltose binding protein (MBP), S-tag. Lex a DNA binding domain (DBD) fusions, GAL4 DNA binding domain fusions, and herpes simplex virus (HSV) BFF6 protein fusions. A fusion protein also can be engineered to contain a cleavage site located between the MTTGH polypeptide-encoding sequence and the heterologous protein sequence, so that the MTTGH polypeptide can be cleaved and purified away from the heterologous moiety.

Many kits for constructing fusion proteins are available from companies such as Promega Corporation (Madison, Wis.), Stratagene (La Jolla, Calif.), CLONTECH (Mountain View, Calif.), Santa Cruz Biotechnology (Santa Cruz, Calif.), MBL International Corporation (MIC; Watertown, Mass.), and Quantum Biotechnologies (Montreal, Canada; 1-888-DNA-KITS).

3.3 Obtaining Polypeptides
MTTGH polypeptides can be obtained, for example, by purification of polypeptides from M. tuberculosis, expressed by of MTTGH polynucleotide(s) and other appropriate methods as will be appreciated by those skilled in the art in view of the teachings herein. In a specific example, the inventors have expressed poly His-tagged enzyme in E. coli and have purified it.

3.4 Protein Purification
MTTGH polypeptides can be purified from any cell which expresses the enzyme, including host cells which have been transfected with MTTGH enzyme expression constructs. A purified MTTGH enzyme polypeptide is separated from other compounds which normally associate with the MTTGH enzyme polypeptide in the cell, such as certain proteins, carbohydrates, or lipids, using methods well-known in the art. Such methods include, but are not limited to, size exclusion chromatography, ammonium sulfate fractionation, ion exchange chromatography, affinity chromatography, and preparative gel electrophoresis. A preparation of purified MTTGH polypeptide is at least 80% pure; preferably, the preparations are 90%, 95%, or 99% pure. Purity of the preparations can be assessed by any means known in the art, such as SDS-polyacrylamide gel electrophoresis.

4. Polynucleotides
An MTTGH polynucleotide can be single- or double-stranded and comprises a coding sequence or the complement of a coding sequence for an MTTGH polypeptide. A coding sequence for MTTGH polypeptide of SEQ ID NO: 2 is shown in SEQ ID NO: 1.

Degenerate nucleotide sequences encoding MTTGH polynucleotides, as well as homologous nucleotide sequences which are at least about 50, 55, 60, 65, 60, preferably about 75, 90, 96, or 98% identical to the nucleotide sequence shown in SEQ ID NO: 1 also are triacylglycerol synthase-like enzyme polynucleotides. Percent sequence identity between the sequences of two polynucleotides is determined using computer programs such as ALIGN which employ the FASTA algorithm, using an affine gap search with a gap open penalty of −12 and a gap extension penalty of −2. Complementary DNA (cDNA) molecules, species homologs, and variants of MTTGH polynucleotides which encode biologically active MTTGH polypeptides also are MTTGH polynucleotides.

4.1 Identification of Polynucleotide Variants and Homologs
Variants and homologs of the MTTGH polynucleotides described above also are MTTGH polynucleotides. Typically, homologous MTTGH polynucleotide sequences can be identified by hybridization of candidate polynucleotides to known MTTGH polynucleotides under stringent conditions, as is known in the art. For example, using the following wash conditions: 2xSSC (0.3 M NaCl, 0.03 M sodium citrate, pH 7.0), 0.1% SDS, room temperature twice, 30 minutes each; then 2xSSC, 0.1% SDS, 50° C. once, 30 minutes; then
matches within the test hybrid is calculated. For example, the polymerase chain reaction (PCR), or a technique such as the polymerase chain reaction (PCR), or is approximately the length of the hybrid in basepairs. MTTGH DNA molecules can thereafter be replicated using molecular biology techniques known in the art and disclosed in manuals such as Sambrook et al. (1989). An amplification technique, such as PCR, can be used to obtain additional copies of polynucleotides of the invention. The inventors have successfully demonstrated this approach. Alternatively, synthetic chemistry techniques can be used to synthesize MTTGH polynucleotides. The degeneracy of the genetic code allows alternate nucleotide sequences to be synthesized which will encode a MTTGH polypeptide having, for example, an amino acid sequence shown in SEQ ID NO: 2 or a biologically active variant thereof.

4.3 Expression of Polynucleotides

To express a MTTGH polynucleotide, the polynucleotide can be inserted into an expression vector which contains the necessary elements for the transcription and translation of the inserted coding sequence. Methods which are well known to those skilled in the art can be used to construct expression vectors containing sequences encoding MTTGH polypeptides and appropriate transcriptional and translational control elements. These methods include in vitro recombinant DNA techniques, synthetic techniques, and in vivo genetic recombination. Such techniques are described, for example, in Sambrook et al. (1989) and in Ausubel et al., CURRENT PROTOCOLS IN MOLECULAR BIOLOGY, John Wiley & Sons, New York, N.Y., 1989.

A variety of expression vector/host systems can be utilized to contain and express sequences encoding a MTTGH enzyme polypeptide. These include, but are not limited to, microorganisms, such as bacteria transformed with recombinant bacteriophage, plasmid, or cosmid DNA expression vectors; yeast transformed with yeast expression vectors, insect cell systems infected with virus expression vectors (e.g., baculovirus), plant cell systems transformed with virus expression vectors (e.g., cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or with bacterial expression vectors (e.g., Ti or pBR322 plasmids), or animal cell systems.

The control elements or regulatory sequences are those nontranslated regions of the vector enhancers, promoters, 5' and 3' untranslated regions which interact with host cellular proteins to carry out transcription and translation. Such elements can vary in their strength and specificity. Depending on the vector system and host utilized, any number of suitable transcription and translation elements, including constitutive and inducible promoters, can be used. For example, when cloning in bacterial systems, constitutive promoters such as the hybrid lacZ promoter of the BLUESCRIPT plasmid (Stratagene, LaJolla, Calif.) or pSPORT1 plasmid (Life Technologies) and the like can be used. The baculovirus polyhedrin promoter can be used in insect cells. Promoters or enhancers derived from the genomes of plant cells (e.g., heat shock, RUBISCO, and storage protein genes) or from plant viruses (e.g., viral promoters or leader sequences) can be cloned into the vector. In mammalian cell systems, promoters from mammalian genes or from mammalian viruses are preferable. If it is necessary to generate a cell line that contains multiple copies of a nucleotide sequence encoding an MTTGH polypeptide, vectors based on SV40 or EBV can be used with an appropriate selectable marker.

5. Host Cells

According to certain embodiments of the subject invention, an MTTGH polynucleotide will need to be inserted into a host cell, for expression, processing and/or screening. A host cell strain can be chosen for its ability to modulate the expression of the inserted sequences or to process the expressed MTTGH polypeptide in the desired fashion. Such modifications of the polypeptide include, but are not limited to, acetylation, carboxylation, glycosylation, phosphorylation, lipidation, and acylation. Posttranslational processing.
which cleaves a “prepro” form of the polypeptide also can be used to facilitate correct insertion, folding and/or function. Different host cells which have specific cellular machinery and characteristic mechanisms for post-translational activities (e.g., CHO, HeLa, MDCK, HEK293, and W138), are available from the American Type Culture Collection (ATCC; 10801 University Boulevard, Manassas, Va. 20110-2209) and can be chosen to ensure the correct modification and processing of the foreign protein.

Stable expression is preferred for long-term, high yield production of recombinant proteins. For example, cell lines which stably express MTGGH polypeptides can be transformed using expression vectors which can contain viral origins of replication and/or endogenous expression elements and a selectable marker gene on the same or on a separate vector. Following the introduction of the vector, cells can be allowed to grow for 12 days in an enriched medium before they are switched to a selective medium. The purpose of the selectable marker is to confer resistance to selection, and its presence allows growth and recovery of cells which successfully express the introduced MTGGH sequences. Resistant clones of stably transformed cells can be proliferated using tissue culture techniques appropriate to the cell type. See, for example, ANIMAL CELL CULTURE, R. I. Freshney, ed., 1986.

5.1 Detecting Expression

A variety of protocols for detecting and measuring the expression of a MTGGH polypeptide, using either polyclonal or monoclonal antibodies specific for the polypeptide, are known in the art. Examples include enzyme-linked immunosorbent assay (ELISA), radioimmunoassay (RIA), and fluorescence activated cell sorting (FACS). A two-site, monoclonal-based immunoassay using monoclonal antibodies reactive to two non-interfering epitopes on a MTGGH polypeptide can be used, or a competitive binding assay can be employed. These and other assays are described in Hampton et al., SEROLOGICAL METHODS: A LABORATORY MANUAL, APS Press, St. Paul, Minn., 1990) and Maddox et al., J. Exp. Med. 158, 12111216, 1983).

5.2 Expression and Purification of Polypeptides

Host cells transformed with nucleotide sequences encoding MTGGH polypeptide can be cultured under conditions suitable for the expression and recovery of the protein from cell culture. The polypeptide produced by a transformed cell can be secreted or contained intracellularly depending on the sequence and/or the vector used. As will be understood by those of skill in the art, expression vectors containing polynucleotides which encode MTGGH polypeptides can be designed to contain signal sequences which direct secretion of soluble MTGGH polypeptides through a prokaryotic or eukaryotic cell membrane or which direct the membrane insertion of membrane-bound MTGGH polypeptide.

6. Antibodies

Antibodies are referenced herein and various aspects of the subject invention utilize antibodies specific to MTGGH polypeptide(s). As described above, one example of a therapeutic agent may pertain to an antibody. Any type of antibody known in the art can be generated to bind specifically to an epitope of an MTGGH polypeptide. “Antibody” as used herein includes intact immunoglobulin molecules, as well as fragments thereof, such as Fab, F(ab)2, and Fv, which are capable of binding an epitope of an MTGGH polypeptide. Typically, at least 6, 8, 10, or 12 contiguous amino acids are required to form an epitope. However, epitopes which involve non-contiguous amino acids may require more, e.g., at least 15, 25, or 50 amino acids.

An antibody which specifically binds to an epitope of an MTGGH polypeptide can be used therapeutically, as mentioned, as well as in immunochemical assays, such as Western blots, ELISAs, radioimmunoassays, immunohistochemical assays, immunoprecipitations, or other immunochemical assays known in the art. Various immunosassays can be used to identify antibodies having the desired specificity. Numerous protocols for competitive binding or immunoradiometric assays are well known in the art. Such immunoassays typically involve the measurement of complex formation between an immunogen and an antibody which specifically binds to the immunogen. Antibodies useful for embodiments of the subject invention may be polyclonal, but are preferably monoclonal antibodies.

7. Ribozymes

Ribozymes may be one category of test compounds potentially useful as therapeutic agents for treatment of TB infection. Ribozymes are RNA molecules with catalytic activity. See, e.g., Cech, Science 236, 15321539; 1987; Cech, Ann. Rev. Biochem. 59, 543568; 1990, Cech, Curr. Opin. Struct. Biol. 2, 605609; 1992, Couture & Stinchcomb, Trends Genet. 12, 510515, 1996. Ribozymes can be used to inhibit gene function by cleaving an RNA sequence, as is known in the art (e.g., Haseloff et al., U.S. Pat. No. 5,641,673). The mechanism of ribozyme action involves sequence-specific hybridization of the ribozyme molecule to complementary target RNA, followed by endonucleolytic cleavage. Examples include engineered hammerhead motif ribozyme molecules that can specifically and efficiently catalyze endonucleolytic cleavage of specific nucleotide sequences.

Accordingly, another aspect of the invention pertains to using the coding sequence of a MTGGH polynucleotide to generate ribozymes which will specifically bind to mRNA transcribed from the MTGGH polynucleotide. Methods of designing and constructing ribozymes which can cleave other RNA molecules in trans in a highly sequence specific manner have been developed and described in the art (see Haseloff et al. Nature 334, 585591, 1988). For example, the cleavage activity of ribozymes can be targeted to specific RNAs by engineering a discrete “hybridization” region into the ribozyme. The hybridization region contains a sequence complementary to the target RNA and thus specifically hybridizes with the target (see, for example, Gerlach et al., EP 321,201).

Specific ribozyme cleavage sites within a MTGGH RNA target can be identified by scanning the target molecule for ribozyme cleavage sites which include the following sequences: GU, GG, and GC. Once identified, short RNA sequences of between 15 and 20 ribonucleotides corresponding to the region of the target RNA containing the cleavage site can be evaluated for secondary structural features which may render the target inoperable. Suitability of candidate MTGGH RNA targets also can be evaluated by testing accessibility to hybridization with complementary oligonucleotides using ribonuclease protection assays. Longer complementary sequences can be used to increase the affinity of the hybridization sequence for the target. The hybridizing and cleavage regions of the ribozyme can be integrally related such that upon hybridizing to the target RNA through the complementary regions, the catalytic region of the ribozyme can cleave the target.

Ribozymes can be introduced into cells as part of a DNA construct. Mechanical methods, such as microinjection, liposome-mediated transfection, electroporation, or calcium phosphate precipitation, can be used to introduce a ribozyme-containing DNA construct into cells in which it is desired to
decrease MITG1 expression. Alternatively, if it is desired that the cells stably retain the DNA construct, the construct can be supplied on a plasmid and maintained as a separate element or integrated into the genome of the cells, as is known in the art. A ribozyme-encoding DNA construct can include transcriptional regulatory elements, such as a promoter element, an enhancer or UAS element, and a transcriptional terminator signal, for controlling transcription of ribozymes in the cells.

As taught in Haseloff et al., U.S. Pat. No. 5,641,673, ribozymes can be engineered so that ribozyme expression will occur in response to factors which induce expression of a target gene. Ribozymes also can be engineered to provide an additional level of regulation, so that destruction of mRNA occurs only when both a ribozyme and a target gene are induced in the cells.

8. Long Chain TG Hydrolyase Activity in Mycobacterium tuberculosis

8.1 Materials and Methods

Bacterial Strains and Culture Conditions—*M. tuberculosis* H37Rv (ATCC 25618) and Δ-lipY mutant were grown in Middlebrook 7H9 (supplemented with 0.05% Tween 80, 10% oleic acid-albumin-dextrose-catalase enrichement, and 0.2% glycerol) and in Dubos-Tween 80-albunin medium (prepared from Dubos broth base and Dubos medium albumin as per the manufacturer’s instructions). All media were purchased from Difco. *E. coli* DH5α and BL21 Star (DE3) (Invitrogen) used as host strains for cloning and expression experiments were grown on Luria-Bertani broth or agar and, when required, antibiotics were added to the culture media at the following concentrations: carbencillin or kanamycin, 50 µg/ml; hygromycin B, 150 µg/ml for *E. coli*; 75 µg/ml for *M. tuberculosis*. Other chemicals and antibiotics were from Sigma Chemical Co., Fisher Scientific and Calbiochem.

DNA restriction and modifying enzymes were procured from New England Biolabs (Beverly, Mass.).

Induction of lipase genes and TG utilization in *M. tuberculosis* strains under nutrient starvation after hypoxic stress—*M. tuberculosis* H37Rv and Δ-lipY mutant cells were grown under a hypoxic condition essentially as previously described to induce the accumulation of TG inside the mycobacterial cell (7). *M. tuberculosis* cells were inoculated into Middlebrook 7H9, grown aerobically at 37°C in roller bottles to an OD₆₅₀ of 0.8 and were used to inoculate Dubos-Tween 80-albumin medium to an OD₆₅₀ of 0.015, grown up to an OD₆₅₀ of 0.06 and distributed in tubes or in single neck vials containing 0.5 ml space to culture volume and sealed with rubber sleeve caps and slowly stirred on a magnetic stirrer for hypoxic growth up to 12 days. Harvested cells were divided into three sets. The first set was washed in PBS and incubated (0 h). The harvested cells of the second set were washed and resuspended in phosphate-buffered saline (PBS) and incubated at 37°C for 6 h. The cells of the third set were washed, resuspended in normal 7H9-OADC-Tween (7H9) medium instead of PBS and served as a nutrient supplemented control. These differentially treated cells were used to measure induction of lipase gene transcripts by semi-quantitative RT-PCR and to measure the utilization of stored TG. RNA isolation and semi quantitative RT-PCR were performed as described before (7), using the primers shown in Table 1.

Cells from the three sets were autoclaved and total lipids were extracted with chloroform: methanol (2:1; v/v) as previously described (7). The 12 days old wild type *M. tuberculosis* hypoxic culture (10 ml) was also used for labeling with 1 µCi of [¹⁴C]oleic acid (specific activity, 55 Ci/mole; American Radiolabeled Chemicals) for 1 h and then the cells were washed with PBS before incubating in PBS for the next 6 h. Lipids were analyzed by silica gel thin-layer chromatography (TLC) using n-hexane:diethyl ether (9:1; v/v), and the radioactivity in the silica gel corresponding to the TG band was measured using a liquid scintillation counter (Packard). An autoradiogram of the TLC was prepared. The amount of TG was visualized by dichromate/sulfuric acid charring of the TLC plates as described before (15). The chared TLC plate was also scanned for quantification of TG accumulation by using the Alphalnager 2200 Gel Doc system (AlphaInno-tech).

Generation of lipY disrupted mutant of *M. tuberculosis* H37Rv—The lipY gene was disrupted by allelic exchange using specialized transducing phage as described (16). The disruption construct of lipY was made by sequential cloning of a 953-bp 5'-flank (consisting of the first 38 bp of lipY ORF and 915 bp sequence upstream of lipY ORF) and a 789-bp 3'-flank (consisting of last 4 bp of lipY ORF and 785 bp sequence downstream of lipY) of lipY, on either side of resp-hyg-res gene cassette in the cosmide pYUB854. The two flanks were generated by PCR amplification using *M. tuberculosis* H37Rv genomic DNA as template by introducing AflIII and XbaI and HindIII and Spel sites on the ends of the 5'-flanks and 3'-flanks respectively for directional cloning into pYUB854 (Table-2). The Pacl digested recombinant pYUB854 containing lipY disruption construct was introduced in plasmid phAE159 and the recombinant transducing phage obtained after packaging was used to transduce *M. tuberculosis*. LipY disruption by allelic exchange was confirmed by PCR analyses using specific sets of primers and Southern hybridization (Table-2). Ten hygromycin resistant clones were screened by PCR using a set of primers (Δ-F and Δ-R) designed from the deleted part of the lipY gene. The allelic exchange by double cross-over was confirmed with two sets of primers, each representing a outwardly directed hyg primer (H1 and H2) and a primer (primers E and F) in the mycobacterial genome beyond the flanking gene sequences used for making the homologous arms of the disruption construct.

DNA isolation and Southern blotting—Mycobacterial genomic DNA was isolated by the guanidine thiocyanate (GTC) method as described (17). DNA samples were digested with suitable restriction enzyme, separated by electrophoresis in 1% agarose gel, transferred to Nylon membranes (Nytran Plus, Schleicher and Schuell, Keen, N.H.) and hybridized with [α-³²P]dCTP labeled probes. Probe labeling and preparation were performed using Redview [α-³²P]dCTP and rediprime II random priming labeling kit (Amersham Biosciences) as per manufacturer’s instructions.

Cloning and Expression of *M. tuberculosis* lipase/esterase genes in *E. coli*—The 24 open-reading frames (ORFs) were amplified from the genomic DNA of *M. tuberculosis* H37Rv by PCR using Pfu Turbo Hotstart DNA polymerase (Stratagene) and cloned into pET200 D-TOPO expression vector (Invitrogen). The directionally cloned fragments were completely sequenced to confirm the sequence integrity of each expression construct. The constructs were used to transform competent cells of *E. coli* BL21 Star (DE3) (Invitrogen) and the proteins were expressed as N-terminal His tagged (SEQ ID NO: 79) fusion proteins after induction with IPTG according to the manufacturer’s protocols. Total cell lysates from induced cultures were prepared in 0.1 M Tris.HCl pH 8.0 containing 1 mM DTE and used for screening for TG hydrolysis activity of all lip gene products. Untransformed host cell lysate was used as control.
Solubilization and purification of LIPY—In our attempts to produce soluble LIPY protein, we performed IPTG induction in E. coli BL21 Star (DE3) cells at 16 °C, 24 °C and 37 °C for 4 h and 12 h. Inductions were also carried out without using IPTG in Dual Media (Zymo Research). In all cases virtually all the expressed protein was insoluble. To solubilize the insoluble protein, his-tagged LIPY was expressed in 500 ml cultures by induction with 1 mM IPTG at 37 °C for 12 h in LB broth. Total cell lysates were centrifuged at 10,000 g, and the pellet was solubilized in a buffer containing 1% (w/v) sodium lauryl sarcosine, 2 mM sodium dodecyl sulfate (SDS), 25 mM triethanolamine, 1.5 mM CaCl₂, 50 mM sodium phosphate buffer pH 7.0, 300 mM NaCl and 50 µg/ml aprotinin with shaking at 330 rpm at 10 °C for 1 h. The solution was clarified by centrifugation at 16,000 g for 20 min at 4 °C, and the supernatant was loaded onto a 5 ml bed-volume cobalt-affinity resin (TALON, BD Biosciences). Unbound proteins and detergents were removed by washing the resin with 10 bed-volumes of bind/wash buffer containing 10 mM imidazole. The bound protein was eluted in 5 bed-volumes of bind/wash buffer containing 150 mM imidazole followed by 5 bed-volumes of bind/wash buffer containing 250 mM imidazole and 5 ml fractions were collected. Aliquots of fractions collected at each step of the solubilization and purification process were analyzed on 12% SDS-PAGE followed by coomassie staining.

Lipase Assays—Lipase activity was measured by the release of [14C]oleic acid from [14C]triolein (55 mCi/mmole, American Radiolabeled Chemicals) using a modified method of Belfrage and Vaughan (18). The reaction mixture contained 50-100 µg protein from total cell lysates, 0.2 µCi [14C]triolein, 20 mM tricine, 2% gum arabic, 1 µg bovine serum albumin, 100 mM NaCl and 0.1 M Tris HCl pH 8.0 in a total volume of 100 µl. Triolein was emulsified in gum arabic and aliquoted into the reaction mixture at the indicated concentrations prior to the addition of enzyme. After incubation at 37 °C for 2 h, the reaction mixture was extracted with 1 ml chloroform:methanol:hexane (1.25:1.41:1, v/v/v) following the addition of 200 µl 0.1 M NaHCO₃, pH 10.5. The radioactivity released into the upper aqueous phase was measured by liquid scintillation counting. Alternatively, the reaction mixture was acidified with 50 µl 6 N HCl and extracted with 1 ml chloroform:methanol (2:1, v/v). The lipids in the lower organic phase were resolved on silica TLC plates developed in hexane:diethyl ether:acetic acid (65:35:2, v/v/v) and the radioactivity corresponding to the internal oleic acid standard was determined by liquid scintillation counting.

To investigate substrate specificity, sonicated emulsions of 20 mM [14C]dipalmitin or [14C]diolein phosphorylcholine or [14C]dioleyl phosphatidylethanolamine or [14C]hexadecylpalmitate were used. To measure pH stability, the purified enzyme was pre-incubated in the appropriate buffer for 15 min at 24 °C prior to the assay at 37 °C for 2 h. Temperature stability was measured by pre-incubating purified LIPY at the indicated temperature for 15 min prior to assay at 37 °C. The effects of serine-directed reagents like diethyl-p-nitrophenyl phosphate (E-600), phenylmethanesulfonfyl fluoride (PMSF), detergents like SDS, polyethylene glycol tert-octylphenyl ether (Triton X-100), polyethylene glycol sorbitol monolaurate (Twee-20) and various salts were determined by pre-incubating the purified LIPY for 15 min at 24 °C with the indicated concentration of effector prior to the assay at 37 °C for 2 h.

8.2 Results
Idenitity and cloning of M. tuberculosis lipase/esterase genes—M. tuberculosis probably uses fatty acids as a carbon source during its dormancy inside the host (8, 10). Previously, we identified 15 tgs genes in the genome of the pathogen several of which are induced under culture conditions that lead to a dormancy-like state resulting in TG accumulation within the bacterial cell (7). Utilization of stored TG would require a true lipase. However no mycobacterial gene that encodes long-chain TG hydrolase has been identified and characterized. We screened the M. tuberculosis genome for the presence of genes encoding such enzymes. The M. tuberculosis genome contains 21 ORFs annotated as putative lipase/esterase genes. We used the sequence of a putative TG lipase from M. tuberculosis strain W17 in the NCBI database (U76006.1, Acc. No. NCBI AB184141, Bifani et al) to screen the M. tuberculosis H37Rv genome for homologous genes. This approach identified three additional ORFs—Rv1169c, Rv3097c and Rv1834, that we designate as lipX, lipY and lipZ respectively, to be consistent with the present nomenclature of all the other lip genes in the M. tuberculosis genome. We included these three genes along with the 21 previously annotated ‘lip’ genes in our screen for genes encoding true lipases.

Screening of M. tuberculosis lipase/esterase gene products for long-chain TG hydrolase activity—The 24 selected M. tuberculosis ORFs encoding putative lipase/esterase proteins were expressed in E. coli and total cell lysates were assayed for triolein hydrolase activity. Lipase activity above untransformed control was normalized for the expression level of each recombinant protein in the total cell lysate. Triolein hydrolase activity in our standard radiometric assay at pH 8.0 was by far the highest in the lysates of recombinant E. coli expressing LIPY followed by LIPK, LIPL and LIPC that showed much lower activities followed by lysates expressing LIPX and LIPI that had even lower levels of activity. All other lip gene products showed little or no triolein hydrolase activity (Table 3).

Utilization of stored TG and induction of lipase genes by starvation in M. tuberculosis cells grown under hypoxic conditions—In order to test the hypothesis that lipase(s) release fatty acids from TG stores under nutrient-deprived conditions that might be encountered during dormancy, we cultured M. tuberculosis under hypoxic conditions for 12 days, a condition which was previously shown to cause TG accumulation (7), and subsequently incubated these cells in a starvation medium (PBS) to test whether the stored TG was utilized under such conditions. To label the stored TG, we incubated M. tuberculosis cells held under hypoxia for 12 days with [14C]-oleic acid for 1 h and then the labeled cells were incubated in PBS for 6 h. After incubation, about 50% of the labeled TG was utilized under nutrient-deprived condition (FIG. 1A). Accumulation of TG during hypoxia and utilization during starvation was also clearly seen by dichromate/sulfuric acid charring of the silica gel-TLCs of the total lipids (FIG. 1B). The intensity of the TG band showed about 50% decrease after 6 h of incubation in PBS. Cells incubated in nutrient rich medium, used as a control, did not utilize significant amounts of the stored TG (FIG. 1C).

During the TG utilization conditions, the lipase genes involved in the release of fatty acids from TG would be expected to be induced. To test for this possibility, the transcript levels of all the 24 selected ORF’s were measured by semi-quantitative RT-PCR analyses. The transcript level of each lip gene before starvation (0 h), after starvation (6 h-PBS) and after incubation in nutrient rich medium (6 h-719) are expressed as a fraction of the 23S rRNA transcript level of the same sample (FIG. 2A). Most of the lipase genes showed induction of transcript level during incubation for 6 h in PBS. The highest level of induction after 6 h starvation was seen in the transcripts of lipY, lipE, lipC, lipZ, lipL and lipI. Since the lip gene products manifested very different degrees
of TG hydrolase activity, the possible relative contributions of the lipase genes to the hydrolysis of stored TG within the mycobacterial cell were assessed by multiplying the transcript level after 6 h starvation with the triolein hydrolase activity of each expressed gene product. Such an analysis showed that LIPY had by far the greatest potential for hydrolyzing in vivo stores of TG in the mycobacterium under such conditions (FIG. 2B).

Disruption of lipY in M. tuberculosis—LIPY showed the highest capacity to hydrolyze long chain TG among all the probable lipase gene products of M. tuberculosis cloned and expressed in E. coli. Moreover, when the organism was subjected to a nutrient deprived state after the cells had accumulated TG under hypoxia, lipY was found to be the most highly induced gene. These results suggested that LIPY is most likely to be the major lipase involved in the hydrolysis of the stored TG. To test for this possibility, we generated a lipY knock-out mutant of M. tuberculosis (FIG. 3). lipY was disrupted by allelic exchange using specialized transducing recombinant mycobacteriophage phAE159 (16). In the constructed lipY deletion allele, 1258 bp out of 1314 bp of total lipY gene sequence was replaced with a hygromycin resistance gene cassette (res-hyg-res) flanked by res (resolvase recognition sequence) sequences.

The clarified supernatant from the lipY mutant cells was subjected to SDS-PAGE with an apparent molecular weight that was slightly lower than the theoretically predicted value of 45 kDa. The purified enzyme eluted from a pre-calibrated Superose-6 gel-filtration column just after the void volume suggesting that the purified, recombinant LIPY exists as aggregates (data not shown).

Biochemical characterization of the TG hydrolase activity of LIPY—The purified recombinant LIPY protein showed very high activity in our standard radiometric triolein hydrolysis assay. Lipase activity increased linearly with time and protein concentration (FIGS. 5A, B). LIPY displayed typical Michaelis-Menten kinetics (FIG. 5C) and the apparent K_m and V_max values were calculated to be 7.57 mM and 653.3 nmol/mg/min respectively from the rectilinear double-reciprocal plot. LIPY hydrolyzed [14C]triolein at a lower rate (316.8±29.0 nmol/mg/min). LIPY did not show any fatty acid release when incubated with phosphatidylcholine, phosphatidyl ethanolamine or hexadecyl palmitate (data not shown).

Inhibitors of lipases are generally classified into groups that act on esterases and lipases. LIPY showed the highest potential for hydrolyzing the TG stored inside the M. tuberculosis cell, as indicated by previously published data (19). The product of lipY would encode a protein with a predicted molecular weight of 45 kDa and a calculated temperature for 15 min. The lipase activity of LIPY dropped sharply when the enzyme was held at 50°C or higher (FIG. 6C). LIPY was stable in storage and retained nearly all of its original activity even after 60 days at 4°C and after 4 cycles of freezing at −20°C followed by thawing. The effect of various detergents on LIPY was investigated. LIPY was stimulated slightly by SDS at concentrations up to 2 mM above which the activity was severely inhibited (FIG. 7A).

The inhibition by SDS was partially reversed by Triton X-100 and 20% of the original activity was recovered (data not shown). Tween-20 inhibited LIPY at all concentrations from 0.1-2.0% (FIG. 7C). Many lipases require calcium for activity but LIPY was inhibited by CaCl_2, CoCl_2, MnCl_2, ZnCl_2, and MgCl_2 also inhibited the activity. However, NaCl, KCl, sodium acetate and potassium acetate enhanced the activity (Table 4).

LIPY, a member of the HSL family—Thirty of the 24 putative lipase/esterases can be classified as lipases belonging to the HSL family (12) and LIPY was the only protein out of the twenty-four with a putative TG hydrolase activity as annotated in the database (19). The product of lipY would encode a protein with a predicted molecular weight of 45 kDa and a pI of 4.5. However, it showed only 9-21% global amino acid identity with the other lipase/esterase-like proteins in the mycobacterial genome (Table 5). Pair-wise alignment of the amino acid sequence of LIPY with 35 representative lipases from all the eight reported families of bacterial lipases (20) indicated that LIPY shared only 12-23% global amino acid identity with known bacterial lipases. However, LIPY possesses the conserved active-site motif GDSAG L (SEQ ID NO: 61) characteristic of the HSL family. Since the crystal structures of the Bacillus subtilis breifelinA esterase and the Archaeoglobus fulgidus carboxylesterase which belong to the HSL family have been elucidated (21, 22), we used the Cn3D Version 4.1 software from the Entrez System at NCBI to produce a structure-based sequence alignment of LIPY with the members of the HSL family. The alignment of conserved domains produced by Cn3D was then used to align other selected members of the HSL family by ClustalW multiple
sequence alignment program. The multiple sequence alignment output from ClustalW was then adjusted manually to achieve maximum similarity between the amino acid sequences. As shown in FIG. 8, this alignment revealed a high degree of similarity between the C-terminal half of the α and other members of the HSL family. This region of high similarity includes the catalytic domain with the consensus pentapeptide GDSAG (SEQ ID NO: 61) containing the active serine residue and the strictly conserved HOGG (SEQ ID NO: 68) motif of unknown function (23) located immediately upstream of the active site consensus motif. The aspartate and histidine residues of the active-site are also conserved with the other members of the HSL family.

Amino acid identity of lipase genes were compared by pairwise alignment with LIPY, which had the highest TG hydrolase activity, using the ALIGN software program at Genestream (http://www2.igh.cnrs.fr/bin/align-guess.cgi). We identified these genes as putative lipases as described in Experimental Procedures.

What is claimed is:

1. A method of screening for agents that modulate *Mycobacterium tuberculosis* triacylglycerol hydrolase (MTTGH) comprising the steps of i) contacting a test compound with a *Mycobacterium tuberculosis* triacylglycerol hydrolase (MTTGH) polypeptide, and ii) detecting binding of said test compound to said MTTGH polypeptide, wherein a test compound which binds to said MTTGH polypeptide is identified as an agent for modulating the activity of *Mycobacterium tuberculosis* triacylglycerol hydrolase.

2. A method of screening for agents that modulate *Mycobacterium tuberculosis* triacylglycerol hydrolase (MTTGH) comprising the steps of i) determining the activity of a MTTGH polypeptide in the presence or in the absence of a test compound, and ii) identifying a test compound that modulates the activity of a MTTGH polypeptide as a potential agent for modulating the activity of *Mycobacterium tuberculosis* triacylglycerol hydrolase.

3. A method of screening for agents that modulate *Mycobacterium tuberculosis* triacylglycerol hydrolase (MTTGH) comprising the steps of i) determining the activity of a MTTGH polypeptide in the presence of a test compound, ii) identifying a test compound that modulates the activity of a MTTGH polypeptide and iii) comparing activity of step (i) with step (ii), wherein a test compound that modulates the activity of MTTGH polypeptide is identified as an agent for modulating the activity of *Mycobacterium tuberculosis* triacylglycerol hydrolase.

4. The method of claim 1, further comprising the step of obtaining a cell which has been engineered to express a MTTGH polypeptide and wherein the step of contacting is in or at the surface of said cell.

5. The method of claim 4, wherein the cell is in vitro.

6. The method of claim 1, wherein the step of contacting is in a cell-free system.

7. The method of claim 1, wherein the polypeptide is coupled to a detectable label.

8. The method of claim 1, wherein the compound is coupled to a detectable label.

9. The method of claim 1, wherein said MTTGH polypeptide comprises a ligand bound thereto and the test compound displaces said ligand.

10. The method of claim 1, wherein the polypeptide is attached to a solid support.

11. The method of claim 1, wherein the compound is attached to a solid support.

12. A method of screening for agents that modulate *Mycobacterium tuberculosis* triacylglycerol hydrolase (MTTGH) comprising the steps of i) contacting a test compound with a MTTGH polynucleotide, ii) detecting binding of said test compound to said MTTGH polynucleotide, wherein a test compound that binds to said MTTGH polynucleotide is identified as a potential agent for modulating the activity of *Mycobacterium tuberculosis* triacylglycerol hydrolase.

13. The method of claim 12 wherein the nucleic acid molecule is RNA.

14. The method of claim 12, further comprising the step of obtaining a cell which has been engineered to express a MTTGH polynucleotide wherein the contacting step is in or at the surface of said cell.

15. The method of claim 12 wherein the contacting step is in a cell-free system.

16. The method of claim 12 wherein polynucleotide is coupled to a detectable label.

17. The method of claim 12 wherein the test compound is coupled to a detectable label.

18. A recombinant cell host containing a purified MTTGH polynucleotide or a recombinant vector comprising a MTTGH polynucleotide, wherein said MTTGH polynucleotide is SEQ. ID No. 1, or a sequence having at least 90 percent identity therewith.
