**ABSTRACT**

Methods, systems and devices for a waveguide pumping gain guided index antiguided fiber laser having a fiber selected for a refractive index crossover at a wavelength between a pump wavelength and a laser emission wavelength. A waveguide pumping system pumps a light having a pump wavelength into the fiber allowing a laser light to be captured by a gain guided process in the core while the pump light, propagating in the cladding is coupled to the core. The fiber selection includes selecting a fiber with a cladding material having a refractive index less than a core material refractive index for a pump wavelength and a core refractive index at the laser emission wavelength is less than the cladding refractive index at the same laser emission wavelength to allow the pump light to propagate through the cladding as a conventional wave guided fiber laser, while the laser emission is captured within the core as an index antiguided, gain guided wave.

FIELD OF THE INVENTION

This invention relates to fiber lasers and, in particular, to methods, systems and apparatus for a gain guided index antiguided fiber laser designed to function as conventional index guiding fiber for pump wavelength and like a gain guided index antiguided fiber for signal wavelengths.

BACKGROUND AND PRIOR ART

Originally proposed by Siegman in his 2003 paper, the concept of gain guiding comes about from the analysis of the V parameter of an optical fiber when the imaginary component of the refractive index is taken into account. The V parameter is the controlling factor in the mode propagation of standard index guiding fibers. Using the V parameter in numerical mode solvers the mode characteristics of an optical fiber or waveguide can be determined. Usually the V parameter is a real number that only takes into account real refractive index. The imaginary component comes about as a result of either loss or gain in the medium that light is propagating through. The V parameter of a waveguide is given by the following equation:

\[ V = \frac{2\pi n}{\lambda} \sqrt{(n_0 + \Delta n)^2 - n_i^2} \]  

where \( a \) is the radius of a fiber-core or half width of a slab waveguide, \( n_c \) is the cladding index and \( \Delta n \) is the index step between the core and cladding. A plane wave propagating in a medium with some gain or loss \( \Delta \alpha \) will propagate according to

\[ e^{-\frac{2\pi n_{\Delta \alpha}}{\lambda} r} \]

the propagation constant in this expression is rewritten as

\[ \frac{2\pi (n_0 + \Delta n)}{\lambda} + j\Delta \alpha = \frac{2\pi (n_0 + \Delta n) + j(\lambda/2\pi\Delta \alpha)}{\lambda} = \frac{2\pi (n_0 + \Delta \delta)}{\lambda} \]

where \( \delta \) is the complex refractive index step which encompasses both index and gain/loss. With this knowledge, the V parameter is rewritten as the complex V-squared parameter to take into account this gain factor.

\[ \psi^2 = \left[ \frac{2\pi n_0^2}{\lambda} \right] \left[ (n_0 + \Delta n)^2 - n_i^2 \right] = \left( \frac{2\pi n_0}{\lambda} \right) 2n_0\Delta n + \frac{\lambda}{2\pi} \Delta \delta \]

The approximation holds for small index steps and gain. Using numerical mode solving techniques for optical fibers one can use the V-squared parameter to determine the propagation characteristics of modes in an optical fiber which has both gain and index traits. Siegman plots (U.S. Pat. No. 6,751,388) an example of such calculations for the first two modes of a fiber. FIG. 1 is a plot showing the mode boundaries and mode propagation regions for the LP_{01} and LP_{11} modes of a cylindrical gain-guiding step-profile in the complex \( \Delta n, \Delta \alpha \) plane.

As shown in FIG. 1, the propagation of a mode depends upon the value of the index and gain steps. Pure gain guiding can occur in a medium with no index step if the gain term \( \Delta \alpha \) is large enough to support the LP_{01} mode shown above the first solid line. A combination of negative or positive index difference between core and cladding and a gain or loss step also allows modes to be supported. The \( \Delta \alpha \) axis gives the imaginary part of the V-squared parameter, which can be calculated from the imaginary component of the previous equation. The benefit of gain guiding is that because \( \Delta \alpha \) is fairly small, relatively large cores, which are represented by \( \alpha \) in the equation (3), is used and single mode oscillation is maintained. In standard index guided fibers the V parameter is fixed, because it is a function of the refractive index and the core size. In gain guided fibers the gain can be changed to compensate for larger cores regardless of the type of glass material used.

Deficiencies of prior art include the fact that gain guided index antiguided fibers are difficult to pump efficiently, despite a large promise of emitting a single transverse laser mode from a very large core and conventional index guiding large mode area fibers are limited to core sizes of around 25 microns for single mode operation, resulting in a limitation on the possible power produced in the fibers due to high power densities. Even these complex designs have only been proven to be single mode for sizes of <100 micron core sizes. High power non-fiber based lasers like CO2, solid state crystal or thin disk have difficulty reaching high powers and high beam qualities and other large mode area concepts and designs are far more complex and hence expensive to manufacture including Photonic Crystal Fibers or Chirally Coupled Core fibers etc. Currently work on such complex designs has been limited to silica fiber, which may be disadvantageous for some rare earth ions, like Thulium, which require high doping percentages to work efficiently.

Therefore there is a need of finding a solution of the pumping problem in gain guided index antiguided fiber lasers for practical use as a laser gain medium with the gain guided index antiguided fiber designed to act like a conventional fiber (index guiding) for pump wavelength, and like a gain guided index antiguided fiber (index antiguiding) for signal wavelengths.

SUMMARY OF THE INVENTION

A primary objective of the invention is to provide methods, systems and devices for a an index crossover gain guided index antiguided fiber laser made of fibers as long as it is necessary in length. Longer length reduces thermal issues, while smaller on can be compact and with much lower non-linearity. A secondary objective of the invention is to provide methods, systems and devices for an index crossover gain guided index antiguided fiber laser having a very large mode area with single transverse laser mode to allow very high powers to be generated in a single mode without causing damage to fiber end facet.
A fourth objective of the invention is to provide methods, systems and devices for an index crossover gain guided index antiguided fiber laser having an all fiber design makes cooling simpler and more efficient.

A fifth objective of the invention is to provide methods, systems and devices for an index crossover gain guided index antiguided fiber laser with a simple to manufacture fiber design will lead to inexpensive fibers.

A first preferred embodiment of the invention provides a waveguide pumping gain guided index antiguided fiber laser including a gain guided index antiguiding fiber having a refractive index crossover at a wavelength between a pump wavelength and a laser emission wavelength, the fiber having a core and a cladding and a waveguide pumping system to produce a pump light having a pump wavelength, the pump light pumped into the refractive index crossover gain guided-index antiguided fiber, wherein the refractive indices of the core and cladding of a gain guided index antiguiding fiber are selected so that the laser light is captured by the gain guided process in the core and the pump light propagating in the cladding is effectively coupled to the core.

Alternative pumping systems can be used including end-pumped into one end of the using fiber based coupling with an output coupler spaced with an opposite end of the fiber; end-pumped into one end of the fiber using fiber based coupling and having an output coupler butt coupled with an opposite end of the fiber; a tapered fiber bundle for uniform pump light distribution along a length of the fiber for uniform thermal distribution; a v-groove side pumping system, the fiber v-grooves directly on a fiber side wall as where pump light is injected through the cladding and coupled into a first cladding after undergoing a total internal reflection at a glass-air interface of the v-groove facet; or a mechanical structure to hold and align a laser diode array and the fiber for side pumping the fiber and having a cooling system coupled with the mechanical structure for cooling the laser diode array and the fiber.

A second embodiment provides a method for producing a waveguide pumping gain guided index antiguided fiber laser comprising the steps of selecting a gain guided index antiguiding fiber having a refractive index crossover at a wavelength between a pump wavelength and a laser emission wavelength, providing a waveguide pumping system to produce a pump light at a pump wavelength and pumping the pump light into the gain guided index antiguiding fiber, the refractive indices of a core and a cladding of the gain guided index antiguiding fiber are selected to allow a laser light to be captured by a gain guided process in the core while the pump light propagating in the cladding is effectively coupled to the core. The gain guided index antiguided fiber selection step includes selecting a fiber material including a cladding material and a core material, the cladding material having a cladding refractive index less than a core refractive index for a wavelength of optical pumping radiation from the waveguide pumping system and further selecting the fiber material for a laser emission wavelength, the core refractive index of the core material at the laser emission wavelength is less than the cladding refractive index at the same laser emission wavelength to allow the pump light to propagate through the cladding as a conventional wave guided fiber laser, while the laser emission is captured within the core as an index antiguided, gain guided wave.

Further objects and advantages of this invention will be apparent from the following detailed description of preferred embodiments which are illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 is a plot showing the mode boundaries and mode propagation regions for the LP01 and LP11 modes of a cylindrical gain-guiding step-profile in the complex Δn, Δω plane.

FIG. 2 is a plot showing the mode propagation regions for LP01 and LP11 modes of an optical fiber in the complex Δn, Δω plane.

FIG. 3 is a graph showing threshold values of the normalized gain parameter G for the LP01 mode in a gain guided index antiguided fiber plotted verses negative values of the index step parameter ΔN.

FIGS. 4a, 4b, and 4c show an example of an Excel sheet with the parameters of the first diode end pumped gain guided laser.

FIG. 5 is a schematic diagram of a gain guided index antiguided fiber longitudinally-pumped by a fiber-coupled laser diode.

FIG. 6a shows the pump light traveling back and forth through the core of a conventional fiber to give useful laser emission.

FIGS. 6b shows pump light trapped between the core and the clad in an index anti grading fiber.

FIG. 7 is a side view of side-pumping a fiber.

FIG. 8 is a graph showing the refractive index crossover wherein the clad and the core cross over beyond a certain wavelength.

FIG. 9a is a graph showing an example of refractive index crossover for a set of glass.

FIG. 9b is a graph showing another example of refractive index crossover for a different set of glass.

FIG. 10 is a schematic diagram of a refractive index crossover gain guided-index antiguided fiber laser.

FIG. 11 is a schematic of refractive index crossover gain guided-index antiguided fiber laser using tapered fiber bundles.

FIG. 12 is a schematic of the v-groove side pumping of a fiber.

FIG. 13 is a side view of an index crossover gain guided index antiguided fiber laser module.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

Before explaining the disclosed embodiments of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangements shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

It would be useful to discuss the meanings of some terminology used herein and their applications starting with a description of index antiguiding. Originally it was thought that only pure gain guiding was plausible, which means that a near zero index step must be created and maintained if the fiber is to gain guide in single mode only which is not an easy feat to produce in the real world. Recently however, it has come to light that strong index antiguiding would work in a laser cavity as disclosed in U.S. Pat. No. 6,751,388 issued to Siegman on Jun. 15, 2004. This means that a fiber could be produced with the opposite index step as would normally be used, essentially not allowing light to propagate in the core. The plot in FIG. 2 shows that single modes can also exist in the index antiguiding regime.

Further into the negative index guiding regime the threshold gain required is significantly decreased. This is a significant benefit because in pure gain guided fibers it is difficult to
dope a fiber with enough ions and be able to pump it hard enough to create the gain guiding effect. Implementing the novel index antiguiding regime according to the present invention significantly lowers the requirement for the maximum gain, and hence makes gain guiding a feasible technique. FIG. 3 is a graph showing threshold values of the normalized gain parameter $G$ for the $L_{P_{01}}$ mode in a gain guided index antiguided (GG IAG) fiber plotted versus negative values of the index step parameter $\Delta N$. As shown in FIG. 3, as the real part of V-square $-\Delta N$ is increased, the required imaginary V-squared parameter $G$ decreases, meaning far less gain is required to achieve gain guiding. As a result, the index antiguiding concept allows fibers to be fabricated with reasonable doping levels that can be pumped with reasonable pump powers.

For purpose of example, and not limitation, a flash-lamp pumped gain guided index antiguided fiber laser was demonstrated with a single mode (M$^2$ at approximately 1.5) laser action in a 10% trivalent Neodymium (Nd$^{3+}$) doped and 1% Nd$^{3+}$ doped, phosphate glass fiber with varying core diameter from 100 $\mu$m to 400 $\mu$m. The fiber has a strong index antiguiding with a $\Delta N$ greater than approximately 1256. The 10% Nd$^{3+}$ fiber had 250 $\mu$m cladding with a 100 $\mu$m core, whereas 1% Nd$^{3+}$ doped fiber had core diameter varying from 100 $\mu$m to 400 $\mu$m in 100 $\mu$m steps. In the example with 1% Nd$^{3+}$ doped fiber the cladding was approximately 1.67 times the core diameter, the length of the fiber was approximately 13 cm and only approximately 8.5 $\mu$m was pumped by the lamp. The length of fiber was placed inside a capillary tube and this tube was placed inside a flash-lamp chamber. The laser was pumped with up to approximately 90 J of light from the flash lamp, with a coupling efficiency of less than approximately 3x10$^{-4}$. The lamp operated at 1 Hz with a pulse duration of approximately 350 microseconds and an HR at approximately 1050 nm mirror was used as one end of the laser cavity. The other end of the fiber included either an approximately 4% Fresnel reflection or output couplers with varying reflectivity predicted by the model.

Progress in gain guided fiber lasers has lead to the development of a simple model for determining the proper output coupler of the laser. Without the proper choice of output coupling, gain guiding can not be obtained because of the nature of the gain guiding modes. In Siegman’s analysis the modes in a gain guided fiber have a threshold behavior based upon the gain achieved in the fiber and on the fiber parameters themselves. These two parameters are $\Delta N$ and $G$, the real ($\Delta N$) and imaginary ($G$) parts of the V-Squared parameter for a fiber. These two terms are given by:

$$\Delta N = 2n_0 \Delta n \left( \frac{2\alpha}{\lambda} \right)^2$$

$$G = \frac{n_0 \lambda}{2\pi} \left( \frac{2\alpha}{\lambda} \right) \cdot g$$  \hspace{1cm} (4)  \hspace{1cm} (5)

where $\Delta N$ is the index step in the fiber, negative for anti index fibers used here, $n_0$ is the fiber index, $\alpha$ is the fiber core radius and $g$ is the gain in the fiber. For obtaining a single mode beam the two lowest order modes ($L_{P_{01}}$ and $L_{P_{11}}$) are the most important to consider. For the strongly anti-index guided regime these modes have a threshold imaginary part of the V-Squared parameter of $G_{th}$, which can be approximated by the following equations when $\Delta N$ is less than approximately $-50$:

$$G_{th} \approx \sqrt{\frac{133.8}{-\Delta N}} \quad \text{for } L_{P_{01}}$$

$$G_{th} \approx \sqrt{\frac{862.2}{-\Delta N}} \quad \text{for } L_{P_{11}}$$

For single mode gain guiding to occur, the $G_{th}$ for the $L_{P_{11}}$ mode can not be exceeded, and this means that the $g$ (gain) in the laser must be kept below a given value based on this $G_{th}$. If this $G_{th}$ for the $L_{P_{11}}$ mode is exceeded the fiber will gain guide in the multimode regime. By setting equations 2 and 4 equal and substituting equation 1 for $\Delta N$ one can determine an expression for the threshold gain $g$ for the $L_{P_{11}}$ mode. This is given by

$$g_{th L_{P_{01}}} = \frac{\lambda^2}{2\alpha} \sqrt{\frac{862.2}{32n_0^2 \lambda^2 \Delta n}}$$

Along the same lines, the gain $g$ must also be large enough to allow the $L_{P_{01}}$ mode to exist, if this is not met the fiber will not gain guide at all. By combining equations 5 and 6 and substituting equation 4

$$g_{th L_{P_{01}}} = \frac{\lambda^2}{2\alpha} \sqrt{\frac{133.8}{32n_0^2 \lambda^2 \Delta n}}$$

is obtained.

A final consideration for this threshold situation is the gain for laser oscillation. This is gain required in addition to the gain for gain guiding to occur, so this must be added to the $L_{P_{11}}$ threshold to determine if the total laser gain will exceed the $L_{P_{11}}$ threshold. The gain for a laser to oscillate is given by the expression

$$g_{osc} = \frac{\ln(R_1 R_2)}{2\alpha} + \alpha$$

where $R_1$ and $R_2$ are the reflectivities of the two cavity mirrors, $\alpha$ is the cavity loss in inverse centimeters. With these three gain criteria it can be determined if gain guiding occurs in a particular fiber. Table 1 shows conditions for different gain guided fiber operating regimes as examples of the different situations that can occur.

Fiber core is doped with approximately 1%Nd\(^{3+}\). The cavity is made with a high reflector at pump-end of the fiber and approximately R=98% output coupler at the other end. Several color filters are used to block the leaked pump light. For this fiber to lase in single mode, the output coupler needed to be in the range of approximately 95 to approximately 99% reflecting.

There are limitations to the purely gain guided index antiguided fiber including the pumping scheme. Conventional fibers are pumped through their ends using dichroic mirrors or fiber Bragg gratings which allow pump light to pass into the fiber while reflecting the signal light. This allows all-fiber based systems have high power and yet be compact in size. End pumping relies on the so called double clad fiber in which there is a rare earth ion doped core and a glass cladding outside the core. Conventional fiber cladding has a lower refractive index than the core but a higher index than that of polymer coating or outside air. As a result of the index profile, the glass cladding or "pump cladding" contains the pump light and as the light propagates it passes in and out of the core, thus being absorbed and producing gain in the core of the fiber as shown in FIG. 6a. The signal emission light generated in the core is then confined in the core by total internal reflection at the core cladding interface resulting in an end pumping scheme that is highly efficient and simple to implement.

The cavity loss has a large effect on whether gain guiding occurs. Selecting an appropriate value for the loss is key in using the model to properly predict an output coupler for use. The cavity alignment can be changed to change the loss in the cavity and thus to induce or restrict gain guiding, making up for being off in estimates of loss. FIGS. 4a, 4b, and 4c show an example of an Excel sheet with the parameters of the first diode end pumped gain guided laser entered. This model can be further honed and tested as more gain guided fiber lasers are made and their results are compared to the theory of the model.

When placed in the chamber and exposed to the pumping several observations were made to suggest laser action was occurring in the fiber. First the output power from the fiber increased at a pump value of approximately 15 J, suggesting a threshold behavior. Second, the spectrum of the laser output narrowed significantly from approximately 10 nm below threshold to approximately 1 nm width centered at approximately 1052 nm above the threshold pump value. Relaxation oscillation spikes were observed in the output from the laser, further suggesting laser action. Using a camera placed at the laser output, the beam profile is observed above and below threshold. After the threshold the beam becomes very round and Gaussian in nature, suggesting single mode LP\(_{00}\) oscillation in the cavity. When the HR mirror is removed, the above phenomena cease showing laser action indicating that the gain guided index antiguided fiber is lasing in a single mode.

The second example demonstrates a single mode with M\(_2\) approximately equal to 1.2 laser action in 1% Nd\(^{3+}\) doped phosphate glass gain guided index antiguided fiber. The core/clad diameter of the gain guided index antiguided fiber was approximately 200 \(\mu\text{m}/334 \mu\text{m}\). FIG. 5 is a schematic diagram of an example of the novel gain guided index antiguided fiber longitudinally-pumped by a fiber-coupled laser diode emitting at approximately 803 nm. The fiber has strong index antiguiding −\(\Delta n\) approximately equal to 5027. The gain index antiguided fiber was mounted in an approximately 0.5 mm deep V-groove filled with thermal grease in an approximately 1-cm thick aluminum plate and the plate was mounted to a water-cooled heat sink plate. The length of the fiber was approximately 2.5 cm and only about 1 cm of the fiber from the pumping side was cooled. In this example the fiber core is doped with approximately 1%Nd\(^{3+}\). The cavity is made with a high reflector at pump-end of the fiber and approximately R=98% output coupler at the other end. Several color filters are used to block the leaked pump light. For this fiber to lase in single mode, the output coupler needed to be in the range of approximately 95 to approximately 99% reflecting.

There are limitations to the purely gain guided index antiguided fiber including the pumping scheme. Conventional fibers are pumped through their ends using dichroic mirrors or fiber Bragg gratings which allow pump light to pass into the fiber while reflecting the signal light. This allows all-fiber based systems have high power and yet be compact in size. End pumping relies on the so called double clad fiber in which there is a rare earth ion doped core and a glass cladding outside the core. Conventional fiber cladding has a lower refractive index than the core but a higher index than that of polymer coating or outside air. As a result of the index profile, the glass cladding or "pump cladding" contains the pump light and as the light propagates it passes in and out of the core, thus being absorbed and producing gain in the core of the fiber as shown in FIG. 6a. The signal emission light generated in the core is then confined in the core by total internal reflection at the core cladding interface resulting in an end pumping scheme that is highly efficient and simple to implement.

The problem with the end pumped gain guided index antiguided fiber is that conventional end pumping cannot be used efficiently because any light introduced into the cladding can not easily penetrate into the core because of total internal reflection at the clad-core boundary. FIG. 6b shows pump light trapped between the core and clad in an index anti grading fiber. Conversely, as shown in FIG. 6c, the pump light travels back and forth through the core of a conventional fiber wherein \(n_{\text{core}}\) is greater than approximately \(n_{\text{clad}}\) to give useful laser emission. As shown in FIG. 6d, pump light trapped between core and clad never gets a chance to pass through the core. Unabsorbed pump light between core and clad is a loss which lowers the efficiency of gain guided index antiguided fiber laser. In the gain guided index antiguided fibers the refractive index of core is lower than the refractive index of the cladding, just the opposite of a conventional fiber.

One way of avoiding this limitation is to excite the core of the fiber with pump light from the side either using a diode bar or flash-lamp along the length of the fiber as shown in FIG. 7 which is a side view of side-pumping a fiber. The side-pump configuration also has the problem of sonic pump light getting trapped between the core and the cladding for the reasons explained above in regard to the index antiguided fiber. There is also a Fresnel reflection loss from the surface of the fiber, unless the entire fiber in AR coated at pump wavelength. The problem is that anti reflection coating the surface of a fiber is expensive and tedious.

Another difficulty with side-pumping a fiber is that much of the launched pump light is leaked through the fiber because of the small core diameter, and unless special arrangement is made to reflect back the leaked power, the efficiency of the gain guided index antiguided fiber laser is poor. For example, a gain guided index antiguided fiber with core diameter of approximately 500 \(\mu\text{m}\) and an absorption coefficient of approximately 35 \(\text{cm}^{-1}\), corresponding to approximately 10 wt % of Nd\(^{3+}\) dopant, absorbs approximately 83% of the launched pump in a single pass. This absorbed power reduces to approximately 26% of the incident power using an approximately 100 \(\mu\text{m}\) core diameter fiber. Also, heavy doping (10-20

</table>
may be destroyed or melted due to the resulting high thermal load. By selecting a material using the novel refractive index crossover concept, the gain guided-index antiguiding fiber laser using tapered fiber bundles and a combination of pumping techniques. FIG. 10 is a schematic diagram showing an example end-pumped from one end of the fiber for a refractive index crossover gain guided-index antiguided fiber laser.

Selecting a refractive index crossover gain guided-index antiguided fiber having a core diameter within a range of approximately 100 to approximately 500 μm as the gain medium provides the desired gain and spreads the pump light over a long enough length to reduce thermal effects. In an embodiment, pump light is provided through the end using standard free space or fiber based coupling methods. The other end of the fiber has an output coupler spliced or butt coupled to it, or simply Fresnel reflection, to make the output end of the cavity.

In the example of end-pumping from both ends of the fiber, a dichroic mirror at one end of the fiber at an angle between approximately 10 to approximately 45 degree is used. Using the dichroic mirror pump light can be coupled into the fiber and signal light can be taken out of the cavity.

FIG. 11 is a schematic of refractive index crossover gain guided-index antiguided fiber laser using tapered fiber bundles to get uniform pump distribution along the length of the fiber and hence uniform thermal distribution. FIG. 11 shows an example of longitudinal pumping of a refractive index crossover gain guided index antiguided fiber using commercially available tapered fiber bundles. Each 'A' represents one of the various legs of the tapered fiber bundles where pump light is coupled either using free space optics or fiber coupled to a laser diode can be spliced directly to these legs. Using tapered fiber bundles the pump power is distrib-
uted across the length of the gain fiber, resulting in uniform pumping and hence uniform thermal distribution.

In a second embodiment the refractive index crossover gain guided index anti guiding fiber laser uses a side-pumping pump light having Fresnel reflection loss at the fiber surface. While the fibers may be anti reflection coated at pump wave-length, anti reflection coating the surface of a fiber is expensive and tedious. In addition, as previously presented, unless special arrangements are made to reflect the leaked pump light back into the fiber, the efficiency of the laser is poor due to low absorption in the core.

In another embodiment, the refractive index crossover gain guided index anti guiding fiber laser is side pumped using v-groove side pumping. FIG. 12 is the schematic of a v-groove side pumping technique. In this embodiment V-grooves are made directly on fiber side walls as shown in the figure. Pump light is injected through the clad, and coupled into the first cladding after undergoing a total internal reflection at the glass-air interface of the v-groove facet. The reflected light cone is guided if its angular spectrum is within the first cladding acceptance angle.

In yet another embodiment, the side pumping is accomplished using a laser diode array. This relatively simple and readily available method uses collimated diode bars to pump a few centimeter length of highly doped refractive index crossover gain index anti-guided fiber. In an example the “gain guided module” consists of a mechanical structure to hold and align the bar and fiber which also provides cooling to both the fiber and diode. FIG. 13 is a schematic of an example of an index crossover gain guided index anti-guiding fiber laser module using a diode bar.

As shown in FIG. 13, the module contains a section of refractive index crossover gain guided index anti-guided fiber that is easily spliced or simply butt coupled on high reflector mirror or even a fiber Bragg grating. A second mirror or fiber grating can be added to the other end of the module to create the resonant cavity in the laser if the Fresnel reflection is not sufficient. The length dimension of the module is scaled in a range of approximately one centimeter to several centimeters depending on the length of the diode bar package. Several 1 cm standard diode bar packages could be lined up to make one long gain guided module. These modules could be made into a free standing moderate power lasers which would result in short, gain guided fiber lasers if designed to have a sufficient length with enough pump power mirrors to attain continuous wave lasing. Cooling water can be used to cool both the bar and gain guided fiber from a single chiller. Alternatively, water cooling is completely avoided when a suitably efficient fan/air cooled heat sink is used. A moderate power index crossover gain guided index anti-guided fiber laser can be made using approximately 5 to 7 watt single emitters, in which case the diode bar in the schematic is replaced with a single emitter and line generating lens system. The single emitter significantly reduces the size of the overall module.

Yet another embodiment, the index crossover gain guided index-antiguided fiber laser uses evanescent coupling for side pumping for evanescent coupling of pump light into the core of the fiber. Due to the effects of evanescent coupling between contacting waveguides, pump light is then coupled into the core. This embodiment works similarly in the refractive index crossover gain guided index anti-guided fiber because the refractive index crossover gain guided index anti-guided fiber is a conventional fiber for pump wavelengths. The benefit of using evanescent coupling is that they are compact and require little alignment, especially compared to the bulk gain guided module previously described and shown in FIG. 13.

An efficient clad to core evanescent coupling leads to an all-fiber based compact system. Because the refractive index crossover gain guided index anti-guided fiber can be used in almost any conceivable fiber laser configuration it is clear that it can be used with a huge range of rare earth ion dopants. Any rare earth ion could be used to dope a gain guided fiber laser system and hence provide emission in a range from approximately 1 micron (Nd, Yb) to approximately 4.5 microns (Tb) in wavelength from ions like Sm, Pr, Ho, Yb, Er, Nd, and Tb. Most rare earth ions have already been made into fiber lasers, so they can clearly be made into an index crossover gain guided index anti-guided fiber laser. These rare earth ions can also be easily doped into any refractive index crossover ceramic, polymer, and crystalline materials.

We claim:

1. A gain guided index anti-guided fiber laser comprising:
   - one single gain guided index antiguiding fiber having a refractive index crossover at a wavelength between a pump wavelength and a laser emission wavelength, the fiber having a core and a cladding, the refractive index crossover condition requiring core and cladding material be selected for a refractive index of the cladding material less than the refractive index of the core material at the wavelength of optical pumping radiation and the refractive index of the core material being less than the refractive index of the cladding material at the laser emission wavelength; and
   - a pumping system to produce a pump light having a pump wavelength, the pump light pumped into the refractive index crossover gain guided-index anti-guided fiber, wherein the refractive indices of the core material and cladding material of the one single gain guided index anti-guided fiber are selected so that the laser light at the laser emission wavelength is guided by the gain guiding process in the core and the pump light at the pump wavelength that is different than the laser emission wavelength propagating in the fiber is effectively coupled into the core via an index guiding process.

2. The fiber laser of claim 1, wherein the gain guided index anti-guiding fiber comprises:
   - a rare earth ion doped material having an index dispersion property of the refractive index crossover for the pump wavelength and laser wavelength that are significantly different such that pump light is index guided and laser light is index anti-guided in the core, wherein the rare earth ion doped material includes a combination of materials that can be pulled into fibers and display the refractive index crossover and that does not alter the index dispersive properties to negate the crossover properties of pump wavelength and signal wavelengths with a change in refractive index with respect to temperature.

3. The fiber laser of claim 2, wherein the rare earth ion doped material is selected from a group consisting of:
   - Thulium based laser material having a pump wavelength approximately 790 nm and approximately 2000 nm laser wavelength, and Ytterbium-Erbium based laser material having a pump wavelength approximately 975 nm and approximately 1500 nm laser wavelength.
4. The fiber laser of claim 2, wherein the rare earth ion doped material is selected from a group consisting of: Samarium, Praseodymium, Holmium, Thulium, Erbium, Ytterbium, Neodymium, and Terbium.

5. The fiber laser of claim 1, wherein the pump light is end-pumped into one end of the refractive index crossover gain guided-index antiguided fiber using fiber based coupling, the fiber laser further comprising:

an output coupler spliced with an opposite end of the fiber.

6. The fiber laser of claim 1, wherein the pump light is end-pumped into one end of the refractive index crossover gain guided-index antiguided fiber using fiber based coupling, the fiber laser further comprising:

a mechanical structure to hold and align a laser diode array and the fiber for side pumping the fiber; and

a cooling system coupled with the mechanical structure for cooling the laser diode array and the fiber.

10. A method for producing an optically pumped gain guided index antiguided fiber laser comprising the steps of:

selecting one single gain guided index antiguiding fiber having a refractive index crossover at a wavelength between a pump wavelength and a laser emission wavelength comprising the steps of:

selecting a fiber material having an optical dispersion consisting of:

selecting the fiber material including a cladding material and a core material, the cladding material having a cladding refractive index less than a core refractive index for a wavelength of optical pumping radiation from the waveguide pumping system; and

further selecting the fiber material for a laser emission wavelength, the core refractive index of the core material at the laser emission wavelength is less than the cladding refractive index at the same laser emission wavelength to allow the pump light to propagate through the cladding as a conventional wave guided fiber laser, while the laser emission is guided within the core as an index antiguided, gain guided wave;

providing a waveguide pumping system to produce pumping optical radiation at a pump wavelength; and

pumping the pump light into the one single gain guided index antiguiding fiber, the refractive indices of a core and a cladding of the gain guided index antiguiding fiber are selected to allow a laser light emission wavelength to be guided by a gain guiding process in the core while the pump light at the pump wavelength that is different from the laser emission wavelength, propagating in the fiber is effectively coupled into the core via an index guiding process.
