A method and system for separating hydrogen and sulfur from hydrogen sulfide (H₂S) gas being produced from oil and gas waste streams. The hydrogen sulfide (H₂S) gas is first passed into a scrubber and filtration unit where it encounters polysulfide solution. Elemental sulfur is freed when the H₂S interacts with the solution, the sulfur is filtered through a porous media such as a ceramic frit, and continues to a stripper unit where the excess H₂S is removed from the sulfide solution. The excess H₂S returns to the scrubber and filtration unit, while the sulfide solution passes into a photoreactor containing a semiconductor photocatalyst such as Cadmium Sulfide (CdS), Platinized Cadmium Sulfide, Pt-CdS, Zinc Sulfide, ZnS, Zinc Ferrate, ZnFe₂O₄, Indium Sulfide, In₂S₃, along with a 450-500 nm light source.

This invention relates to sulfur recovery from oil and gas refinery waste streams, and in particular to a method and apparatus for sulfur recovery from oil and gas refinery waste streams using semiconductor particulates, where hydrogen sulfide (H2S) having been absorbed into an alkaline solution is decomposed in a photochemical scheme to yield both sulfur and hydrogen which can be later sold or used internally at a refinery and claims the benefit of priority of Provisional Application 60/126,036 filed on Mar. 25, 1999, by the same inventors thereof.

BACKGROUND AND PRIOR ART

Oil refineries typically pump crude oil from the ground which contains unusable organic sulfur, the latter of which must be separated from the crude oil in order to allow the oil to become a useful product. Typically, the pumped crude oil is treated with hydrogen and a catalyst under a high temperature which decomposes the organic sulfur in the crude oil and releases the sulfur in the form of hydrogen sulfide (H2S) gas. The problem is what do the refineries do with the H2S gas, which is a noxious poisonous gas that cannot be released into the atmosphere.

Recent environmental regulations generally require oil and gas refineries to develop waste minimization technologies for the treatment of sulfur-containing compounds, such as hydrogen sulfide (H2S) within their facilities. Current technology typically requires a solvent absorption and stripping process to separate the acid gases, a Claus type reactor to perform a partial oxidation of the sulfide to make elemental sulfur and water and a tertiary gas treatment. The latter is decomposed at the plant.

As the world supply of petroleum decreases, the average sulfur content of crude oil has begun to rise. In recent years the average oil refinery has gone from being a net producer of sulfur and water and a tertiary gas treatment. The latter is decomposed at the plant.

SUMMARY OF THE INVENTION

A primary objective of the present invention is to provide a method of recovering sulfur from oil and gas refinery waste streams using semiconductor particulates, where hydrogen sulfide (H2S) having been absorbed into an alkaline solution is decomposed in a photochemical process to yield both sulfur and hydrogen.

The secondary objective of the present invention is to decompose noxious poisonous gas such as hydrogen sulfide into separate amounts of hydrogen and sulfur using light and a photocatalyst.

A third objective is to recoup the H2 contained in H2S and return it to the hydrodesulfurization plant for reuse in oil refinery applications.

A preferred embodiment of the novel process decomposes H2S in a thermodynamically uphill process to its constituent elements:

H2S+light→S+H2

The energy to drive the reaction can either come from the sun or an artificial light source. The decomposition process is photoelectrochemical in nature, in which the photovoltaic effect from semiconductor solid state physics is combined with conventional electrochemical principles to produce a light-driven electrochemical reactor using semiconductor electrodes. Thus, we call it the PEP (photoelectrochemical particle process).

In the preferred embodiment, H2S from the stripper is passed into an alkaline solution to produce bisulfide ion, HS−(aq). The sulfide solution is then sent into a photoreactor, which consists of a bed of catalyst-activated semiconductor particles such as Cadmium Sulfide (CdS), distributed in a thin, planar or cylindrical array depending on the lamp configuration, and a light source containing a wavelength range of approximately 450 to approximately 500 nm. As the solution is passed over the surface of the photo-energized semiconductor particles, bisulfide ion is oxidized and water is reduced to sulfur and hydrogen, respectively. Other photo-catalysts useful can include as Platinized Cadmium Sulfide, Pt-CdS, Zinc Sulfide, ZnS, Zinc Ferrate, ZnFe2O4, and Indium Sulfide, In2S3.

The exit stream from the photoreactor will contain sulfur in the form of polysulfide ion, which results when sulfur is produced in the presence of excess bisulfide ion:

HS−+(n−1)S2−+OH−→S2+n−2H2O

30

The polysulfide solution is returned to the scrubber tank, where pressurizing with H2S causes the sulfur to become separated from solution.

The following chemical process shows the effects of combining sulfur recovery and scrubber units, utilizing the acid properties of H2S itself to decompose polysulfide ions and free the elemental sulfur.

S2−n+H2S→(n−1)S2n−2H2S−

Further objects and advantages of this invention will be apparent from the following detailed description of a presently preferred embodiment which is illustrated schematically in the accompanying drawings.

BRIEF DESCRIPTION OF THE FIGURES

FIG. 1 is a layout of the photoelectrochemical particle (PEP) process for H2S decomposition for sulfur recovery.

FIG. 2 shows how a semiconductor particle works for sulfur recovery.

FIG. 3 shows a flowchart of the chemical formula reaction occurring in the layout of FIG. 1.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Before explaining the disclosed embodiment of the present invention in detail it is to be understood that the invention is not limited in its application to the details of the particular arrangement shown since the invention is capable of other embodiments. Also, the terminology used herein is for the purpose of description and not of limitation.

FIG. 1 is a layout system of the photoelectrochemical particle (PEP) process for H2S decomposition for sulfur recovery. The system consists of three major units: A, the scrubber and filtration apparatus; B, an outgassing stripper unit such as an H2S stripper, and the like; C, the photoreactor. The scrubber used would be akin to a wet scrubber
used in gas cleaning applications such as but not limited to the scrubber unit used in U.S. Pat. No. 5,211,923 to Harkness et al., which is incorporated by reference. Hydrogen sulfide \( \text{H}_2\text{S} \) coming from a source such as a hydrosulfurization plant, a sour natural gas well and the like, is bubbled into scrubber and filtration apparatus A, by line 5 where it encounters polysulfide solution 10 coming from photoreactor 70. An outlet 20 with control valve 25 is in place to maintain an overpressure of \( \text{H}_2\text{S} \) in the head space and to function as a pressure relief valve. The \( \text{H}_2\text{S} \) lowers the pH of the scrubber vessel solution 30, to approximately 7.0 to approximately 7.5, whereupon the polysulfide anion decomposes, freeing elemental sulfur, \( \text{S}^0 \). The sulfur is collected by filtration 40 of the suspension through a porous material such as ceramic frit, and the like.

The filtrate continues by line 45 into the stripper unit B, where the excess \( \text{H}_2\text{S} \) is removed from the sulfide solution. The pH of the solution rises to the 10 to 12 range, depending on the extent of \( \text{H}_2\text{S} \) removal. The \( \text{H}_2\text{S} \) is returned through line 50 to the front line of the scrubber unit A, while the sulfide solution 60 is fed to the photoreactor C containing immobilized photocatalyst. The sulfide solution inside the photoreactor 70, consisting mainly of bisulfide ion, \( \text{HS}^- \), is oxidatively converted to elemental sulfur and then complexed with excess bisulfide ion to make polysulfide ion, \( \text{S}_2\text{H}_2\text{S}_4^- \), while water is reduced to make \( \text{H}_2\text{O} \), under the action of light source 80. The photocatalyst can be a plated cadmium sulfide, \( \text{CdS} \). See for example N. Buhler, et al., Photochemical Hydrogen Production with Cadmium Sulfide Suspensions, J. Phys. Chem., Vol. 88(1984) pp.3261. Other photocatalysts such as zinc sulfide, \( \text{ZnS} \), zinc ferrate, \( \text{ZnFe}_2\text{O}_4 \), indium sulfide, \( \text{In}_2\text{S}_3 \), and the like would also additionally have a photocatalytic effect on \( \text{H}_2\text{S} \). See Ueno et al., Silica-Supported \( \text{ZnS} \) Cds Mixed Semiconductor Catalysts for Photogeneration of Hydrogen, J.Phys.Chem., 89(1985), pp. 3828; Li et al., Hydrogen Production by \( \text{H}_2\text{S} \) Photocatalytic Decomposition, New J. Chem., 16(1992) pp. 517; and Savinov et al., Suspensions of Semiconductors With Microheterojunctions-A New Type of Highly Efficient Photocatalyst For Dihydrogen Production From Solution of Hydrogen Sulfide and Sulfide Ions, Int. J. Hydrogen Energy, 14(1989) pp. 1.

Any broadband visible light source such as a low pressure mercury fluorescent lamp or a tungsten filament bulb, would provide sufficient excitation energy for the photocatalytic reaction. Light sources concentrating their irradiance between approximately 450 to approximately 500 nm would be most effective. This is due to the spectral window created by the absorption edge of the \( \text{CdS} \) photocatalyst on the low energy side and the absorption edge of the background polysulfide solution on the high energy side. Examples of such light sources would be \( \text{Zn} \), and \( \text{Cd} \) spectral lamps and certain special blue fluorescent lamps.

Referring to FIG. 1, the \( \text{H}_2 \) gas percolates out the top of the photoreactor C, while the polysulfide solution is returned to the scrubber unit B. \( \text{H}_2 \) is released out of the top of the photoreactor, underneath “C”. The sulfur is shown as being collected by filtration. Use of a settling tank would also be an alternative. Either way, the sulfur is a solid and would have to be collected by opening up the system. Additionally, the sulfur can be melted and collected in molten state.

It would be important to include excess base to keep pH high and facilitate photocatalytic reaction, since the photodecomposition of HS requires OH as a co-reactant. As previously described a light source having maximum wavelength range of between approximately 450 to approximately 500 nm is needed to penetrate the disulfide solution while remaining within the spectral envelope of \( \text{CdS} \). Use of a reasonably strong acid such as \( \text{HCl}, \text{H}_2\text{SO}_4, \text{H}_3\text{PO}_4 \) can be used to precipitate sulfur from polysulfide solution. From a material supply and cost point of view, it would be desirable to use \( \text{H}_2\text{S} \) (hydrogen sulfide) as the acidic agent.

FIG. 2 shows how a semiconductor particle works for sulfur recovery. FIG. 2 shows the operation of a photocatalytic particle as it would apply to hydrogen sulfide decomposition. The photoparticle is immobilized in a polymer binder and subjected to an ultraviolet(UV) visible radiation source such as sunlight, and the like. Absorption of a photon of light whose energy is greater than the band gap energy of the photocatalytic material results in the creation of an electron/hole pair. The pair represents positive and negative charge carriers that can move independently of each other. Both carriers can be capable of charge transfer into the surrounding solution. The free electron represents reducing, or electron-donating power, while the hole represents oxidizing, or electron accepting, power. Because of the small particle size(on the order of approximately 1 um) the charge carriers can quickly migrate to the particle/electrolyte interface. The electron serves to reduce water to \( \text{H}_2 \) gas and hydroxide ion, while the hole serves to oxidize sulfide or bisulfide ion, depending on the solution pH, to elemental sulfur.

FIG. 3 shows a flowchart of the chemical formula reaction occurring in FIG. 1. The process chemistry associated with each part of the PEP process is shown in FIG. 3. For the system start-up, the scrubber contains only caustic solution, representing some background OH- concentration (210). Hydrogen sulfide is introduced (220), generating HS- and eliminating half of the OH- ion \( \text{H}_2\text{S} \). This solution then goes to the photoreactor, where light absorption by the photocatalyst converts bisulfide ion to bisulfide ion, \( \text{S}_2\text{H}_2\text{S}_4^- \)(230). The resultant solution returns to the scrubber, where pressurization by \( \text{H}_2\text{S} \) results in the reverse conversion plus the precipitation of elemental sulfur, \( \text{S}^0 \)(240). Stripping away the excess \( \text{H}_2\text{S} \) raises pH and regenerates the initial balance of bisulfide and hydroxide ion(250).

While the invention has been described, disclosed, illustrated and shown in various terms of certain embodiments or modifications which it has presumed in practice, the scope of the invention is not intended to be, nor should it be deemed to be, limited thereby and such other modifications or embodiments as may be suggested by the teachings herein are particularly reserved especially as they fall within the breadth and scope of the claims here appended.

We claim:

1. A method of recovering sulfur from hydrogen sulfide (\( \text{H}_2\text{S} \)) waste streams using a photochemical process in a closed cycle system with semiconductor photocatalyst particulates, comprising the steps of:
   (a) producing hydrogen sulfide (\( \text{H}_2\text{S} \)) having a first pH level;
   (b) raising the first pH level of the hydrogen sulfide(\( \text{H}_2\text{S} \)) to a second pH level being higher than the first pH level;
   (c) interacting the hydrogen sulfide having the second pH level with a photocatalyst particulate; and
   (d) applying light to the photocatalyst particulate and the hydrogen sulfide to separate hydrogen from sulfur; and
   (e) recycling steps (a), (b), (c) and (d), so that the separated hydrogen can be recycled in a closed cycle system.

2. The method of recovering sulfur of claim 1, wherein

3. Further includes:
a source chosen from at least one of:
an oil refinery, a gas refinery, a hydrodesulfurization
plant, or a sour natural gas well.

3. The method of recovering sulfur of claim 1, wherein the
photocatalyst includes:
Cadmium Sulfide(CdS).

4. The method of recovering sulfur of claim 1, wherein the
photocatalyst includes:
Platinized Cadmium Sulfide(Pt-CdS).

5. The method of recovering sulfur of claim 1, wherein the
photocatalyst includes:
Zinc Sulfide(ZnS).

6. The method of recovering sulfur of claim 1, wherein the
photocatalyst includes:
Zinc Ferrate(ZnFe₂O₄).

7. The method of recovering sulfur of claim 1, wherein the
photocatalyst includes:
Indium Sulfide(In₂S₃).

8. The method of recovering sulfur of claim 1, wherein step (d) includes:
a light source having a wavelength of approximately 450
to approximately 500 nm.

9. The method of recovering sulfur of claim 1, wherein the
raising the first pH level of the hydrogen sulfide(H₂S) of
step(b) further includes the step of:
applying a polysulfide solution to the hydrogen sulfide
(H₂S) to form a scrubber solution;
removing a portion of hydrogen sulfide(H₂S) from the
scrubber solution to form a sulfide solution.

10. The method of recovering sulfur of claim 9, wherein the
raising the first pH level of the hydrogen sulfide(H₂S) of
step(b) further includes the step of:
removing excess hydrogen sulfide (H₂S) from the sulfide
solution prior to step (c) so that the sulfide solution
consists mainly of bisulfide ion.

11. The method of recovering sulfur of claim 1 wherein
the first pH level of the hydrogen sulfide(H₂S) has a range
of approximately 7 to approximately 7.5, and the second pH
level of the hydrogen sulfide(H₂S) has a range of approxi­
mately 10 to approximately 12.

12. A method of decomposing hydrogen sulfide(H₂S) to
sulfur(S) and hydrogen(H₂) in a closed cycle system, compr­ising the steps of:
(a) producing hydrogen sulfide (H₂S) having a first pH
level;
(b) passing the hydrogen sulfide (H₂S) having the first pH
level into a polysulfide solution to form a sulfide
solution having bisulfide ions, the sulfide solution
having a second pH level being higher than the first pH
level;
(c) interacting the sulfide solution having the second pH
level with a photocatalyst particulate;
(d) applying light to the photocatalyst particulate and the
sulfide solution to separate sulfur from hydrogen and
form the polysulfide solution; and
(e) recycling the polysulfide solution into step (a) to
repeat in a closed cycle system.
